How long were you consulting engineer for the Guggenheims?

Only two or three years, during which time I brought to their attention at least two properties in which they became interested, first, the Dairy Farm in California, and second, the Utah Copper at Bingham, Utah.

Yes, I had the pleasure of reading the report you made on the Utah Copper in 1905 and I remember particularly your diagnosis of the economic phase of the proposed operation. Why did the Guggenheims drop this business?

They did not drop it; they took up the first convertible bond issue at that time. The common stock was already in the hands of the MacNeill and Penrose group.

If I remember correctly, you were consulted with regard to the drainage system of Cripple Creek?

Yes, I spent a few weeks studying the drainage of the Cripple Creek district in 1902. The situation was an extremely interesting one. Over a large portion of the district, the watercourses were so intimately connected that at a distance of half a mile the water-level would vary only a few feet. One shaft would have no water to pump while another shaft a half-mile away might be pumping one or two thousand gallons per minute at a depth only five or ten feet greater, and when the first

THE RAY CONSOLIDATED COPPER MINE

shaft was sunk twenty feet the burden of the pumping would pass from the second to the first. In this basin at certain horizons it was necessary to remove over a hundred million gallons of water for each foot vertical that was drained. There was very little influx and when once drained the water gave little trouble. The old Standard tunnel discharged 17,000 or 18,000 gallons a minute for a few months and for almost two and a half years discharged an average of over 10,000 gal. per minute. The obvious solution of the problem was a drainage-adit. This plan was adopted and the Roosevelt adit was the first of the drainage-levels driven. David W. Brunton and A. E. Carlton contributed much to the success of the drainage scheme.

As you gradually withdrew from mining affairs in Colorado with what new enterprises did you become connected?

For the first few years much of my work was in connection with the Guggenheim Exploration Company on the Pacific Coast. I resigned in 1905. Early in 1907 the deal for the property now owned by the Ray Consolidated Copper Company came up. Philip Wiseman had seen this property some years before and was enthusiastic with regard to it. We tried for a number of months to get in touch with the right people. John Annan was the controlling spirit among the English group that controlled the Ray at that time, and William Young Westervelt was their American representative. The connection was finally made through Charles H. Cutting, then living in New England, and through Mr. Cutting an understanding was reached with Mr. Annan, then in England. This property had been worked for some time by the English company, but the enterprise had not been profitable and the company was being financed by a small group of stockholders led by John Annan and J. G. Gordon. The earlier attempts to work the mine had been made with the idea that the ore was of rather a high grade. These attempts were initiated before a railroad

was built to the mine. Much development work had been done, part of it under the supervision and direction of Alexander Hill. A concentrator had been constructed and operated, and probably some concentrate had been shipped. This concentrator worked only the richer ore, but the development work had exposed two or three million tons of 2% disseminated ore and the various scattered shafts gave strong indications that the property was to become one of the great copper mines of the world.

Of course, by that time you had the benefit and experience of the Nevada Consolidated and the Utah Copper?

Yes, and it was that experience that made the property seem particularly attractive.

Will you not say something about the acquisition of the Ray property?

When I first saw the Ray, Mr. Cutting and Thomas Kavanaugh had exchanged letters with Mr. Annan in regard to an option. Mr. Kavanaugh was on the property and showed me on my arrival a telegram from a mining operator offering him a cash payment of \$5000 if he would go back on the understanding that he then had with Mr. Wiseman and me. This did not tempt Mr. Kavanaugh for a moment. A complete agreement was finally made with Mr. Annan, and the Ray Consolidated Copper Company was organized with a capital of 600,000 shares of \$10 each and an authorized issue of \$3,000,000 of 6% bonds convertible into stock at \$10. The shareholders of the English company that owned the property took \$400,000 of bonds, 122,500 shares of stock, and \$100,000 in cash for the property, which was deeded to the Ray Consolidated Copper Company. The purchasing syndicate paid \$100,000 in cash to the English company, put \$100,000 into the treasury of the Ray Consolidated Copper Company, and received in consideration thereof \$200,000 par value of bonds and 127,500 shares of stock. The English shareholders gave to the purchasing syndicate an option on 61,250 shares, being half of their hold-

ings, at \$10 per share, this option being valid until February 1, 1909. Mr. Annan laughed at the request for an option on a portion of their stock at \$10 and readily granted it, but before the option period expired the development amply justified the purchase of this stock at that price.

When did Mr. Jackling get into the business?

The original financing was accomplished in February 1907 through Sherwood Aldrich, Eugene P. Shove, Charles L. MacNeill, and Spencer Penrose, all of Colorado Springs. I am not quite sure whether Mr. Jackling was interested in the beginning or not, but shortly afterward he did become interested and soon became chairman of the executive committee and managing director of the company.

Did you and Mr. Wiseman have any interest in the enterprise and do you still retain that interest?

Mr. Wiseman, Mr. Cutting, Mr. Kavanaugh, Robert

THE UNITED EASTERN MINE AND MILL

D. Grant, and I obtained an interest in the stock of the company and all the survivors of our little group are still interested in it.

To what figure did the shares that you bought rise?

I think \$37 per share is the maximum price that has been paid for the stock on a capitalization of 1,600,000 shares. The shares that we bought from the English holders at \$10 were on the basis of six million dollars for the property, the issue at that time being 600,000 shares. At \$37 per share for 1,600,000 the property was valued at close to sixty million dollars. The stock prices for the last few years have usually represented a value of 35,000,000 to 40,000,000 dollars for the mine.

What are the prospects at the present time?

According to the annual report for 1919, the mine had 84,736,384 tons of ore averaging 2.063% copper, with possibilities for increased tonnage through extension of the orebody laterally and to a greater depth in certain portions of the property.

That must have been a most pleasant operation, both technically and financially. What did you do next?

Several smaller ventures followed. A very fortunate opportunity came in 1914 when Frank A. Keith got in

touch with George A. Long and John L. McIver, who then held options on what is now the property of the United Eastern Mining Company. Mr. Long and Mr. McIver had worked underground in the adjoining Tom Reed property and had become convinced that the United Eastern ground would hold the continuation of the orebody. The data they had secured were not altogether convincing and it was only after several months of desultory discussion that an option was obtained from them at \$25,000 for 51% of the stock issued. The shaft that they had started was pushed vigorously. All of the money paid for the stock was spent in exploratory work.

I suppose you would call this a beneficent wild-cat?

Yes, indeed, it was. We were very doubtful about the outcome, quite as doubtful as we have been with regard to many wild-cats that have long since been forgotten. It was one of the fortunate ventures that go to make up for the long years when one seeks and works and spends without any reward whatever.

Who were associated with you in this deal?

Frank A. Keith, Philip Wiseman, C. H. Palmer Jr., George D. Nordenholt, R. I. Rogers, J. E. Fishburn, and W. D. Woolwine.

How did the prospect pan out?

The shaft cut the vein at about 200 ft., but on that level only a few scattering assays were obtained. 250 ft. deeper a cross-cut to the vein went into bonanza, the vein showing from 20 to 25 ft. in width of \$20 to \$25 gold ore. This proved to be the top of a very rich and large ore-shoot. A mill was erected and started in January 1917, and since that time has been running continuously, the tonnage having been gradually increased from about 200 to 300 tons per day.

How much has the mine produced altogether?

About 325,000 tons yielding over \$7,000,000 gross, yielding a profit in excess of \$4,000,000.

How deep is the mine now?

About 1300 feet.

Does the vein look healthy in the bottom?

The vein is of fair size in the bottom, but the ore has become poor. Further development will be done in depth in the hope that the ore may improve, and additional development work is in progress laterally. One of the greatest difficulties for the past two or three years has been the lack of men for work underground.

Speaking of the increased cost of gold mining, I would like to ask you what you think of the proposal to levy an excise of \$10 per ounce on gold, as proposed in the McFadden bill now before Congress?

It impresses me as an extremely ingenuous and plausible proposal, but if passed, it will be because of the backing of the financiers, for there seems to be absolutely no chance of its passage in the interest of the producers of gold. The passage of this bill would increase the production in this country somewhat and the cost of it would be borne not by the Government but by the jewelers and other manufacturers in such a way that the people at

large would feel it very slightly. As to the soundness of it from a financial standpoint, I hardly know what to say. What is your opinion on that?

I think it a form of class legislation to which we ought to resort only in case of extreme national necessity, which I believe does not exist. In any event, unless I am much mistaken, the prospects of the bill passing Congress are and have been extremely small. You have been interested in a sulphur enterprise I believe in Texas, have you not?

Yes, about 1910 I was in charge of an examination of a sulphur property in Texas for a group of New York capitalists led by Bernard M. Baruch. At that time I asked my chief assistant, Spencer C. Browne, to look

This is won by a process quite similar to that developed by Herman Frasch in Louisiana. The sulphur is melted underground by water heated to a temperature of 300° to 350°; after melting, it is pumped to the surface by an ordinary air-lift and is stored in vats made of planking. These vats are as much as 200 ft. wide, 300 to 1000 ft. long, and 30 to 50 ft. high. The sulphur is pumped from underground with little, if any, admixture with water and after being pumped into the vat it cools gradually, and solidifies. When the vat is full and the planking removed one sees an enormous block of solid sulphur lying on the ground. The sulphur is blasted and then loaded by a Brown hoist into railroad-cars.

For what purpose is most of it used?

PUMPS AND PIPING IN THE BOILER-HOUSE OF THE TEXAS GULF SULPHUR CO.

over Texas carefully for other possible sulphur-producing territory. This investigation indicated that the property of the Gulf Sulphur Company, near Matagorda, in Texas, was very promising. Shortly afterward negotiations were started and a stock interest was acquired. By 1917 nearly all the stock of this company, which owned about four hundred acres of ground, had been acquired. Today between two and three thousand acres are controlled. The name of the company has been changed and it is now known as the Texas Gulf Sulphur Company. During 1917 systematic development of the ground was begun, by drilling.

What kind of drilling?

With the rotary oil-rig, which is so commonly used in California. The overlying eight or nine hundred feet of material is made up of occasional layers of limestone in 'umbo', which is a partly consolidated marine mud. The ordinary rotary drill was especially suited to penetrate such material.

How do you win the sulphur?

Much of it is used in the paper trade, much is used in making high-grade acid and also acid for the fertilizer industry, and a considerable tonnage is ground and refined for use in orchards and vineyards.

Can you tell me anything about the financial side of this enterprise, that is to say, how much capital was required and how fruitful it became?

The investment was over six million dollars. The result has been satisfactory, assuring an ample reward for the risk and expenditure involved.

Have you done any mining in foreign countries?

I have done more or less in Mexico, of course, but have never been connected with large operations there. I have been interested in ventures in other foreign countries, but none of them have come to fruition except one in the island of Cyprus. About ten years ago, Mr. Wiseman and I, together with three others who have since died or dropped out of the enterprise, engaged Charles Godfrey Gunther to look for likely property in this country and Mexico. After searching fruitlessly for several

years, it was decided that there was an opportunity around the shores of the Mediterranean. Under Mr. Gunther, search was made in the libraries of this country and Paris and London for information that would guide him to promising districts. On his first trip, after going to the Mediterranean, he started from the Red Sea with a dozen camels and as many cut-throats of the polyglot population and went to Mt. Sinai. There was copper there, but the conditions were not favorable.

Did Mr. Gunther find evidence of any large-scale copper mining operations?

No, not in that district. Apparently some copper had been mined on the Sinai peninsula and the evidences of turquoise mines were numerous. Mr. Gunther then visited a number of places around the Mediterranean, Northern Africa, Spain, Sardinia, Asia Minor, and adjacent regions, but he found nothing of exceptional interest until he went to Cyprus. That island shows the evidences of Roman and Phoenician mining at a number of points, but there are only a few where the slag-heaps indicate that the operations were large. The conditions existing at the place where the largest accumulation of Roman and Phoenician slags was found were so favorable that Mr. Gunther was confident that a mine could be uncovered. This was at Skouriotissa, five or six miles from Morphou Bay and about twenty miles west or south-west of Nicosia, the capital of the island of Cyprus. A prospecting permit covering a square mile was obtained from the English governor of the island. Mr. Gunther then returned to this country and about a year later took back with him a drill such as has been used to develop the 'porphyry' coppers. Drilling was started in the latter part of 1913 or the early part of 1914, and the present orebody was being developed when the War started between Germany and the Allies. Operations were hampered and finally drilling discontinued on account of a lack of supplies and it was not until about a year ago that our drilling was resumed. During the interval, however, Mr. Gunther did a large amount of underground work and built a railroad to the shore at Morphou Bay.

What is the character of the orebody?

The ore is a massive iron pyrite containing about 24% copper, something less than \$1 in silver and gold, 47 to 48% sulphur, and is very free from arsenic and other elements deleterious to acid-making. The orebody now developed covers about twenty acres and has an average thickness in excess of 60 feet with a maximum thickness of 130 feet or more.

What evidences have you found of the work done by the ancients?

There is approximately one million tons of slag on the property, perhaps half of it having been made by the Phoenicians and half by the Romans.

What does the slag assay?

The Phoenician slag contains a little less than 1½% of copper; the Roman slag about ¾%.

Do you think there is any chance of beneficiating any of this slag, especially that left by the Phoenicians?

Yes, there is a possibility of developing very considerable bodies of the concentrated ore as well as additional tonnages of massive sulphides. A smelting operation would probably bring the Phoenician slag into use. There are several depressions in the surface indicating caved stopes below. Some old openings appear on the surface and large areas are covered with dumps from the ancient mining operations. Underground we have cleaned out two or three thousand feet of ancient drifts. These are small, about four feet high, rather less than three feet wide, narrow at the bottom, widening where a man's shoulders would have to pass through, and arched on top. The character of much of the ground was such that these drifts still stand perfectly, except at the intersections, or where the openings were unusually large.

Have you found any ancient implements?

A few lamps, which were made about the time of Christ. Sticks and fragments of pottery have been found, but no implements. Occasionally in the slag-dumps a little metallic copper is detected and one blacksmith's dolly was picked up, fashioned to put a blunt point on copper rods of four different diameters. Several spiral raises with a diameter of about 45 ft. have been opened up. These evidently were used for ingress and egress. At one point there is about an acre of fragments of ancient earthenware pots, which may represent the waste-heap of an ancient sulphur refinery, for in one of the caves the floor was covered to a depth of two feet with material that resembles the ash remaining after distilling sulphur, and in one corner of this ancient cave there was a broken pot partly filled with fine sulphur. Possibly water troubled the ancients and these earthenware pots were used by slaves in carrying water from underground.

You ought to find some implements in the old dumps?

The copper dolly referred to is the only one I know of. *Colonel Mudd, you did a good deal of work for the Government during the War, I believe. Will you please state the nature of it and the impressions that you obtained from it?*

I was one of the assistant-directors of the U. S. Government Explosive Plants, a separate administrative unit, set up by the Secretary of War. D. C. Jackling was director of this unit, whose principal work was the erection of the smokeless-powder plant at Nitro, in West Virginia, which was designed to produce 800,000 pounds of cannon powder per day.

The site selected was a cornfield; it was necessary forthwith not only to build wagon-roads and railroads, and erect the plant itself, but to provide dwellings, bunk-houses, restaurants, stores, Y. M. C. A., church, movies, hospital, electric lights, waterworks, and everything else to accommodate 20,000 people. By August, or within eight months, some powder was being produced in this plant. When the Armistice was signed, a plant with a rated capacity of 800,000 lb. of smokeless powder per day was 90% completed and the daily output had already reached an important figure. The plant included buildings and apparatus for making sulphuric and nitric acids

for the purification and nitrating of the cotton; for poaching, boiling, dissolving, and transforming it into a jelly; for passing this jelly through the dies and drying, testing, packing, and shipping this powder finished and ready for use.

Finished powder varies in size of grain depending on its use. Small-arms powder has over 300,000 grains to the pound. 14-in. cannon powder has seven or eight grains to the pound, each grain being $1\frac{1}{2}$ inch in diameter and $2\frac{1}{2}$ in. long. It looks more like brownish molasses candy than like a violent explosive.

The Nitro plant is located in a bend of the Kanawha river and covers an elliptical area about $3\frac{1}{2}$ miles long and $1\frac{1}{2}$ miles wide. There were in all between 3300 and 3500 buildings constructed. The total expense was \$60,000,000. From first to last 90,000 men were employed at this place, but at no time did the total number of employees exceed 19,000, excluding a military guard of about 500. The usual difficulties prevalent during that period were encountered in securing labor, supplies, and prompt transportation. Privately owned powder-plants grew like mushrooms between 1914 and 1917, and it is a satisfaction to know that America was able to supply not only her own needs but to furnish the Allies with large quantities of smokeless powder from a time shortly after Germany attacked France until the Armistice was signed.

There has been and will be much criticism of war work; but considering the lack of comprehensive general and detailed plans of all that was necessary to carry on a war, the urgency of the need, and the consequent sacrifice of everything to speed, the multitude of new things to be done, and the lack of training for these new duties, I consider the accomplishment of the nation and of nearly all the men with whom I was brought in contact was extremely creditable. The spirit of unselfish service was dominant in Washington and self-interest rarely obtruded itself. Mistakes and inefficiency were common enough, but this was inevitable in anything that had such a marvelously rapid expansion as the war activities of this country. It appears that the personnel of an army can be secured and given some training more rapidly than proper equipment and supplies can be provided. Military training of our young men is extremely desirable, but our people will make a greater mistake if they fail to force Congress to pass such laws and provide such funds as will ensure ample equipment and supplies for any possible future war.

Mr. Mudd, are your sons to become mining engineers?

One of them was graduated from Columbia college as a mining engineer in 1912. The other is studying medicine at the University of California.

How would you compare the condition of the mining industry as you knew it when you started with its status today?

When I started a trained engineer was subject to the sneers and contempt of many of the practical men. That is rapidly disappearing; the engineer is coming into his own. The spectacular development of the past few years

in some of the enormous porphyry coppers has given us a larger perspective; it is not unusual now to look for a property having a life of ten or twenty years instead of as many months.

In other words, the industry has been stabilized?

Yes, decidedly. It is certainly much more satisfactory to have to do with an industry that is stabilized rather than one on which you cannot count from year to year.

How would you compare the standard of conduct obtaining in mining affairs 35 years ago with the present standard?

The standard has been raised very greatly. Collusion and dishonesty between the sellers of machinery and supplies and those in control of mining operations was frequent then, whereas now it is practically unknown. The standard with regard to the selling of stock to the public has also been raised considerably, but it needs further improvement.

How do you regard the opportunities offered to a mining engineer with those that were offered in your time?

They are better. His opportunity to obtain an excellent training with many of the larger corporations and better established engineers is larger and better than it was 35 years ago. The chances for stable and satisfactory employment are much more numerous. The openings for making money, while of a different type, are, I think, greater than they were.

Of course, the salaries paid today to a successful mining engineer and even to a young man are much higher than in your time and mine, and therefore a young man obtains the necessary capital with which to participate in mining operations much sooner than he used to?

Salaries are not only higher, but higher in proportion to the cost of living; opportunities for saving are greater, and the tendency to allow the young men to participate is also increasing.

You believe then that it is a good thing for the members of the profession to participate with their principals?

Yes, I do, but when this is done there must be absolute frankness, and even with this frankness, if the results are not satisfactory, one takes risk of criticism. It is good to risk one's own money on just the same basis as that of the other investors, or one's clients, showing good faith and confidence as completely as possible.

If it were all to do again, would you prefer to be in some other profession?

No, I know of none in which I think I could have gotten as much enjoyment, made as many good friends, and in which I would have had an opportunity to participate in the initiation of work that has meant opportunity and livelihood to so many.

Exports of silver from San Francisco to China in August totaled 1,943,000 oz. The total export of silver into China for 1920 up to the end of August was 51,858,764 ounces.

Anaconda Enterprise in Chile

Although retarded by war conditions and great irregularity in receipt of supplies in South America, the development of the Andes Copper Co. has steadily progressed in the last three years. This company is owned by the Anaconda Copper Co. and part of the proceeds of the two \$25,000,000 bond sales made by Anaconda in the last two years has gone into the development of its subsidiary.

The Andes property is situated about in central Chile, at an elevation of 10,500 ft., 100 miles from the sea-coast. The ore occurs in blanket formation and 120,000,000 tons of ore has been developed. There is still a considerable area to be drilled, in which there is every promise of adding to the ore-reserves.

Sixty miles of railroad connecting with the State railroad at Pueblo Hundido have been constructed and is at the present time in full operation.

The ore will be mined by the caving system, and will require no hoisting, everything being dropped through a system of raises to an adit to be completed within the next three or four months. When finished it will be more than two miles long. The ore will be transported by electric trains to the mill, six miles distant.

A town has been established at the mill-site, modern and up-to-date. An ample supply of water for the property will be brought from the higher points in the Andes, requiring three tunnels, work upon which is being pushed. A supply of water for camp purposes has already been brought into the property.

A great amount of research and experimental work has been done in the laboratory at Anaconda, and a process for the successful treatment of the ore has been definitely selected. Electric power is in use at the mine, generated at the coast in a plant capable of taking care of present needs. A larger power-plant has been fully designed and specifications for the same have been drawn. The whole enterprise has reached a stage where only delay in deliveries, excessive cost of materials and transportation are holding it back, and it is thought unwise to construct such a large plant under present conditions, as the treatment of from 12,500 tons to 15,000 tons of ore per day is contemplated. In the meantime development upon the property is being carried on, the heaviest portion of this work having been almost completed.

The Lo Aguirre and Africana mines, the property of the Santiago Mining Co., another subsidiary of Anaconda, are situated about 20 miles west of Santiago, Chile. The two mines are absolutely different in character. In the Lo Aguirre mine the ore occurs as a blanket deposit of oxidized ore, although recent development on the main haulage-level has shown a body of sulphide ore, averaging approximately 3%, the extent of which is as yet unknown. Winzes are being sunk at the present time to determine its depth. The greatest portion of the development work has been completed at this property, as it will be mined by the caving system.

The Africana mine, some six miles distant, has been

developed through two vertical shafts, the main shaft being 700 ft. deep, from which levels upon the vein have been extended both north and south. The shafts are 2000 ft. apart. The ore in the Africana property occurs in vein formation.

Of course, the speed with which Anaconda brings its South American mines to the producing point depends on the copper market. There is no hurry now for an increased production of metal. But when the market shows some semblance of sustained business, these South American mines are confidently expected by the Anaconda management to be able to lay their metal down in New York as cheaply as, and in many cases more cheaply than, the majority of the mines of North America.

Opening Kegs of Blasting-Powder

It would seem as if opening kegs of black blasting-powder with wooden tools would be a perfectly safe proceeding, but according to a recent bulletin of the Bureau of Mines it is not. Among other things, it says: "Black powder may be ignited by direct impact, and the writer believes that this may occur without presupposing a preliminary spark. It is well known, however, that black blasting-powder is very sensitive to ignition by spark flame, or heated materials, and these may be produced by an electric current, by an open light, by incandescent particles from a pipe, cigar, or cigarette, by the tearing of metal sheets or scraping of metal against metal, and possibly by other means. The above statement will serve to introduce a newly recognized hazard—the ignition of black blasting-powder by the forcible opening of kegs with wooden tools. It has not been definitely established just how opening a keg with a wooden maul, wooden sprag, or a wooden mallet causes explosions, since it appears to be very difficult to strike a spark with wood against metal, but it may be that in breaking the keg, the sharp points of the sheet-iron would be driven inside the keg; that two or more of these points have been made; and that in rubbing over one another, these points or the edges of the strips have caused a spark; or it may be that the strips or points have been driven forcibly against the side of the keg and produced sparks, or it may be that the wooden tool was covered with a gritty substance, thus facilitating sparking, or it may be, and this has been demonstrated at the Explosive Experiment Station of the Bureau of Mines, that the fine particles of black blasting-powder remaining in the angular groove of the chime received the impact from the wooden tool and this ignited the particles.

"Regardless, however, of just how a spark may be produced, the evidence presented clearly condemns the method of opening kegs of black blasting-powder with wooden tools by punching a hole through the top of the keg. The usual 25-lb. black blasting-powder keg is provided with a bung-hole and a cap for closing it, and in all cases, the powder should be poured from the keg through this bung-hole. In view of the menace of other methods of opening the kegs, excuses for their use cannot be given serious consideration."

The Federal Reserve System

By EDWARD ELLIOTT

At its inauguration the Federal Reserve system was looked upon with disfavor and distrust by the majority of bankers, who resented what they regarded as Government interference. Its inestimable service in facilitating war finance through the mobilization of a large part of the financial resources of the country won for it almost universal appreciation, but the general reaction from wartime enthusiasms, the admitted inflation of credit, the high prices and the readjustments attendant upon the post-war period have combined to bring upon the system a variety of criticisms. It is, therefore, important that the organization and principles of the Federal Reserve system should be better understood, and some acquaintance with the events that preceded the enactment of the Federal Reserve Act will aid in a proper appreciation both of the changes in our financial system which it brought about and of the merit of the present plan.

Following the Civil War there was a period of high prices and credit expansion, which ended in the panic of 1873. Over-expansion resulted in a crash; deflation was abrupt and destructive. There was no machinery to check inflation or to bring about gradual deflation.

Recovery was slow, but the growth of population and the development of our natural resources were factors that greatly aided in the re-establishment of business prosperity. Yet, twenty years later, in 1893, came another panic of great severity. Again in 1907 the country experienced a panic, which differed from the previous ones in that it was primarily a financial as distinguished from a commercial panic. Business was booming—in fact, it was too prosperous, or rather it had expanded beyond the ability of the banking system of the country to take care of it—and so the panic of 1907 is often spoken of as a banker's panic.

What was then the banking system? In order to aid in financing the Civil War by securing a market for Government bonds, the National Bank Act was passed, by which national banks could be established in the various States of the Union under the supervision of the Comptroller of the Currency. His functions were limited to those of oversight—seeing to it that the National banks were properly organized and operated—or that the final consequences of those which passed into the pale realm of insolvency were performed with due solemnity.

National banks were authorized to issue currency based on U. S. government bonds. This bond-secured currency was fairly profitable for the banks, but it was not elastic in volume; it could not be readily increased or diminished to keep pace with the increase or decrease in the volume of business. In addition to the National banking system, each State had its own banking system. By reason of the tax imposed by national law upon currency issued by State banks, they have ceased to be banks of issue.

The currency of the United States then consisted of national bank notes, gold and gold certificates, silver and silver certificates, 'greenbacks' or U. S. notes, and fractional currency, none of which could be issued by the Government or by the banks in response to the needs of business.

With respect to both the National and State systems, it is to be observed that each was composed of separate and distinct units, in no way co-ordinated save in the matter of administrative supervision.

An important feature in any banking system is its reserve. It seems to be universally agreed that every bank should be required to hold a certain sum, which is fixed at a definite percentage of its deposits, as a reserve to meet the demands of its depositors; what this percentage should be varies from State to State, and in the national banking system and the Federal Reserve system, as well as in the State systems, it varies with the population of the locality and with the character of the deposit, whether commercial or savings. California State banks must maintain a 12% reserve against commercial deposits in a town or city, the population of which does not exceed 50,000; 15% when the population does not exceed 100,000, and 18% when above 100,000, and a 5% reserve against savings deposits. But only half of the reserve must be cash in vault; the other half may be deposited with another bank. While the States vary greatly in the percentage required, California will serve as an example. The same principle held good also for the old National Bank system. The cities under the National system were and still are divided into reserve and central-reserve cities.

For the clearing of checks and other purposes, country banks carry balances with banks in reserve cities and these in turn with banks in central-reserve cities, the balances formerly being composed in part of the reserves permitted by law to be carried in other banks. The practice became general among the city banks to pay interest on the balances carried with them by their correspondents. Against the deposit of the correspondent bank, the city bank was compelled to carry a reserve, half as cash in vault and half with another bank if desired. In order not to lose money by reason of the interest it was paying on bank-balances, the depositary bank was compelled to lend a certain amount of these bank-balances above the reserve requirement, and desire for profit led it to lend as much as it could. The result, then, was a succession of deposits, beginning with the country bank and continuing up to the New York banks. This was known as the pyramiding of deposits. Accompanying this was the lending of the deposits above the reserve up to the limit deemed advisable by each bank.

So long as times were quiet and there were no unusual

demands, the system worked fairly well, but when the country banks had a strong demand for funds and began to withdraw their balances, the city banks found themselves in an awkward position, for they, too, were doubtless having heavy demands from their customers, and to meet the calls of the country banks they began to call upon the banks with which they had made deposits. Finally, the demands converged upon the big New York banks. Having loaned by far the larger part of their deposits, their only resource was to call in their loans. The effect is obvious. The borrowers were called upon to pay at the very time it was most difficult to pay. There was first tight money and if the demands from the country and city banks outside New York continued, then a panic such as that of 1907 might ensue. If New York could not pay, nobody could pay.

Following the panic of 1907 and the discussion it provoked regarding a reform of our banking and currency system, Congress in 1908 appointed a National Monetary Commission, which undertook an exhaustive study of the banking and currency systems of all the important countries of the world. Its report, commonly called the Aldrich report, was made in 1912.

In every important European country there was a central bank, holding the reserves of the banks, serving as a discount market and having the power to issue currency. The report led to the introduction of the Aldrich bill in the Senate. This sought to give to the United States a similar central bank, but the closing months of the Taft administration were not auspicious for the passage of constructive legislation, and nothing was accomplished. President Wilson, upon his inauguration in 1913, called a special session of Congress for the purpose of revising the tariff. After months of effort, the Underwood Tariff Bill was passed late in the summer and Congress had hoped to be allowed to quit the heat of Washington and return home to rest and quiet, but the President addressed the Congress upon the need of banking and currency reform as a necessary complement to tariff revision in order that business might have the advantage of the aid that would come from needed reforms. Weary as it was from the tariff struggle, Congress took up the work of revising our banking legislation, and on December 23, 1913, the Federal Reserve Act was approved by the President.

The purpose of the new legislation was to remedy the evils of the old system by providing a central-reserve system, a steady discount market and a currency elastic in volume. The Aldrich plan had contemplated a central bank controlled by bankers. The Federal Reserve Act provided for a maximum of 12 Regional Reserve Banks, each under its own board of directors and all under the Federal Reserve Board. This Board is composed of seven members, of whom two, the Secretary of the Treasury and the Comptroller of the Currency, are members ex-officio, and five are appointed by the President for a term of ten years. The Federal Reserve Board is the agency through which the administrative centralization of the 12 Federal Reserve banks is achieved, but the powers of the board are not limited to mere matters of

administration for the centralization, or rather unification of operation of the 12 banks, is likewise in its hands since the Board may compel one Federal Reserve bank to re-discount for another.

The 12 Federal Reserve banks have been likened to twelve reservoirs of credit; each member bank has its own pipe-line running to the reservoir and the twelve reservoirs are connected by pipe-lines to a central station, the Federal Reserve Board, which can direct the flow from one bank to another and thus adjust the credit level in all—or, putting it in other terms, the Board can adjust the reserves of the different banks and maintain an average reserve percentage for the system.

Each Federal Reserve bank is governed by a board of nine directors, six of whom are elected by the member banks while three are appointed by the Federal Reserve Board. There are three classes of directors, called A, B, and C, composed of three each. Class C consists of the appointed members, one each year to serve for a term of three years. Class A are elected by the member banks; they are representative of the banks and are generally bankers. Class B are likewise elected by the member banks but are business men. The member banks are divided into three groups according to capitalization so that the capital represented in each group shall be as nearly equal as possible. This results in the few large city banks composing one group, the more numerous medium-sized banks of the larger towns composing another, and the very large number of small country banks the third. Each group elects one Class A and one Class B director once every three years.

This seemingly complicated procedure leads to the choice of three directors, one from each class, each year. The directors choose the Governor, Deputy Governor, and other officers who carry on the active banking operations. The Federal Reserve Board names one of the Class C directors as Federal Reserve Agent and Chairman of the Board. As Federal Reserve Agent he maintains a local office of the Federal Reserve Board in the Federal Reserve bank and serves as the connecting link between the Board and the bank. He also has custody of the Federal Reserve notes which he issues to the bank in return for gold or gold and re-discounted paper.

The growth of the Federal Reserve banks has been extraordinary. When the Federal Reserve Bank of San Francisco was opened for business on November 16, 1914, the entire staff, including janitor and watchman, numbered 22, and occupied a small space at the rear of the Merchants National Bank. Today it overflows a six-story building of its own and is beginning the erection of a permanent building, with more than double the present floor-space. In addition to the head office in San Francisco, there are five branches, at Spokane, Seattle, Portland, Salt Lake City, and Los Angeles; and the staff now numbers more than 1000. The territory embraced within this, the Twelfth Federal Reserve District, includes the States of Arizona (except the five south-eastern counties), California, Nevada, Utah, Idaho, Oregon, and Washington. It is greater in extent and more diversified in activities than any other district.

A Federal Reserve bank is often called a bank for banks. All National banks must be members, and eligible State banks may become members if they wish. A bank becomes a member by subscribing to the stock of the Federal Reserve bank of its district in an amount equal to 6% of its capital and surplus, half of which is paid in gold or gold certificates, and the other half is subject to call. Out of the net earnings of a Federal Reserve bank, its member banks are entitled to a cumulative 6% dividend upon the paid-up capital stock. The rest of the profits go into surplus until the surplus equals the subscribed capital stock; thereafter 10% of the net earnings after payment of dividends goes to surplus and the balance to the Government as a franchise-tax.

There are three fundamental principles of the Federal Reserve system: the centralization of reserves, the ability of member banks to borrow and re-discount, and the note-issue privilege. These three principles are so closely related that the absence of any one of them would render the operation of the system of comparatively little value. Let us consider them in the order named.

Every member bank now carries all its legal reserve with the Federal Reserve bank of which it is a member. The only cash in vault that a member bank need carry is the amount necessary to transact its daily business, or what may be called 'till' money; there is no legal requirement for vault cash. In view of the centralization of reserves and the re-discount facilities furnished by the Federal Reserve banks, the percentage of deposits that must be carried as reserve has been materially lessened. Before the Federal Reserve system went into operation, country National banks carried a 15% reserve against demand deposits; reserve city banks a 25% reserve, part cash and part deposits with other banks, and central-reserve city banks a 25% reserve, all cash. These percentages have been reduced to 7, 10, and 13, respectively, all with the Federal Reserve banks, thereby releasing for investment a large amount of funds previously tied up in idle reserves. The Federal Reserve banks pay no interest on the reserve carried with them. In view of the very large earnings of the Federal Reserve banks, the member banks have begun to urge that they should be paid interest on their reserve.

One of the bad features of the old system was the payment of interest on reserves, for it made it necessary for the depository bank to lend out a large part of these funds. The Federal Reserve banks ought never to be required to pay interest on the reserves. They are essentially reserve institutions and they ought to be free to keep their funds in hand to meet any emergency and not be put under the pressure of earning interest on reserve deposits. Moreover, they are not money-making institutions, paradoxical as that may sound in view of their large earnings. They should never be regarded as money-lenders for their members, lest a spirit should grow up which would lead to their control for the purpose of making money for the members instead of for the purpose of meeting the unexpected or unusual financial strain and stabilizing business and financial conditions. So much has been said on this subject, and bankers are

sometimes so insistent that a larger share of the profits should go to them, that it is worth while seeing what justice there is in their position. The average banker thinks that the profits of the Federal Reserve banks have been made with his money and therefore he should share in them, and that if there were no Federal Reserve bank he would be getting interest from some other bank. Aside from any other advantages that have accrued from the Federal Reserve system, the percentage of reserve has been lowered and the average bank makes rather than loses. The question may be put in this way: Is a high reserve percentage, with low interest on half of it, more profitable than a low percentage with current rate on the amount represented by the difference in percentage? Let us take an example from a bank in a reserve city with \$40,000,000 demand deposits. Under the old system its reserve would be 25%, or \$10,000,000, half cash in vault, earning nothing, and half, or \$5,000,000, with other banks at 2 to 2½%. At the latter rate, the interest per annum would be \$125,000. This the banker thinks he has lost through receiving no interest on his reserve with the Federal Reserve bank. How does the matter stand in reality? As a member, the Reserve city bank with \$40,000,000 demand deposits carries a 10% reserve, or \$4,000,000, with the Federal Reserve bank without interest. But this is \$6,000,000 less than formerly. At 6% the yield would be \$360,000. Assuming that the bank might need \$3,000,000 of this \$6,000,000 as cash on hand or 'till' money, its income from this reserve released would still be \$180,000, or \$55,000 more than under the old scheme. In addition, it has the benefits of the Federal Reserve system. Moreover, the profits of the Federal Reserve banks have been made only through the use of them by the members. Every time a Federal Reserve bank makes a dollar, it is due to the fact that a member bank has borrowed or re-discounted, thereby securing additional funds to lend at a rate higher than the discount rate; or the Federal Reserve bank has bought acceptances in the open market that banks would otherwise have had to carry, and, as acceptances bear a low rate, bank funds are thereby released for more profitable use. As a practical proposition the payment of interest on deposits by the Federal Reserve banks would make them competitors of the city banks to the latter's detriment.

The centralization of reserves would be of little value unless accompanied by the ability on the part of the member banks to borrow from or re-discount with the Federal Reserve banks, since in this way alone can they draw upon the credit reservoir created by pooling reserves. A member bank may borrow from its Federal Reserve bank for a period not to exceed 15 days on its own note, secured either by U. S. government bonds and certificates of indebtedness or by paper eligible for re-discount or purchase. Banks ordinarily do not borrow money, although there may come times in the life of every bank when it is both necessary and proper to borrow, but it is supposed that the occasions will be rare and due to some temporary condition, hence the limit of 15 days put upon the time.

The Federal Reserve system has been subjected to

severe criticism from certain quarters because during the War it permitted the banks to borrow on their notes, secured by U. S. government obligations, and renewed these notes again and again, at the rate of interest borne by the bonds or certificates, sometimes even at a lower rate. This is really a criticism leveled at the method adopted by the Government in financing the War and raises a question that will be debated for years to come.

The opposing views may be stated briefly. The critics say that the bonds should have been issued at a going, or investment, rate, in which case the investors of the country would have bought the bonds and that the policy adopted of issuing the bonds at a 'patriotic' rate led to purchase on credit by people who were patriotic or who thought it desirable to appear so. Credit was thereby expanded and prices rose accordingly. The Federal Reserve banks, by making a low rate on loans secured by Government obligations, contributed to the inflation and filled their portfolios with non-liquid assets while at the same time they lessened their ability to meet the normal commercial needs of the post-war period.

It must be admitted that the credit expansion of the country has been a matter for the most serious consideration for more than six months and that as far back as the first of January the Federal Reserve Board and the Federal Reserve banks have given the matter their most earnest consideration, but they are unwilling to admit the justice of much of the criticism.

When the Government adopted the policy of marketing the bonds at a patriotic rate, the Federal Reserve system moved by the same spirit of patriotism which stirred us all, put itself and its resources at the disposal of the Government. Recognizing that Government obligations under normal conditions ought not to find a place in Federal Reserve bank portfolios, it was also recognized that the conditions were not normal and that to carry on the War successfully, the bonds must be sold; and no one can establish that the bonds could have been sold in any other manner.

In reply to the criticism that the rate should have been an 'investment' rather than a 'patriotic' rate, the view is expressed by some that no reasonable rate would have sufficed to find an investment market for the bonds because there was not surplus capital of 15 or 16 billions in the country. Others take the view that even if present, it would have been disastrous to offer a rate sufficient to attract it, since it would have been drawn away from enterprises necessary to the successful conduct of the War. Moreover, let us recall the psychology of the war days, remembering that at the outbreak of the War money was cheap, and it will be evident that the Government could with difficulty have carried through a program of war finance on any other than a 'patriotic' rate. There were enough slackers and malcontents without adding to their number by giving them opportunity to prate of the War as a rich man's war for the enrichment of Wall Street plutocrats. Moreover, the psychological effect of the patriotic appeal of the Liberty Loan campaigns would have been lost. In con-

clusion of the argument, it is maintained that the inflation, if an evil, was an unavoidable accompaniment of war finance, unless one were willing to strike out on a new and untried course and finance the war entirely by taxation or Government control and operation, at a fixed price for labor and materials, of all industries remotely touching the conduct of the War, which would have meant practically all industries.

In respect to discount operations, the Federal Reserve Act provides that notes, drafts, and bills of exchange made for an industrial, commercial, or agricultural purpose or the proceeds of which have been or are to be used, are eligible for re-discount under regulations to be provided by the Federal Reserve Board. Industrial or commercial paper must have not more than 90 days to run, and agricultural—which includes livestock paper—must not more than six months when presented for discount. No loan that has been made for investment purposes or for the purpose of carrying or trading in stocks or bonds is eligible. In addition to being eligible, paper presented for re-discount must also be acceptable. There must be a reasonable expectation that the paper will be paid at maturity, and to satisfy itself on this score the Federal Reserve banks may require every note presented for re-discount, unless secured by warehouse receipt, bill of lading, etc., to be accompanied by a financial statement of the maker, which must show an excess of quick assets over current liabilities sufficient to warrant the expectation of payment at maturity.

Let us see how the matter works out in practice. We will suppose my credit at my bank is good for \$500 and I borrow this amount on my unsecured note to buy stock or to build a house. If my bank wished to re-discount this note with the Federal Reserve bank, it would ask me to make out a financial statement, if it did not already possess one, and the note, together with a copy of my statement, would be sent to the Federal Reserve bank. There, upon examination of my statement, it would be seen that I was not engaged in business and was not a farmer and that the note had not been made for any one of the purposes allowed by law, and it would not be accepted. If, however, I were a manufacturer buying material with the proceeds, or a merchant buying goods, or a farmer buying hay or fertilizer or cattle, or harvesting my crop, the note would be re-discounted if my statement proved satisfactory.

In the face of the enormous re-discounts of today, it is hard to believe that six years ago, when the system was put into operation, banks were very unwilling to show re-discounts on their statements. The problem then, was to get the banks to use the system; now, it is to find a way to limit them in the amount they may re-discount.

The Federal Reserve Act provides that there shall be no discrimination among member banks but that in accommodating one bank due regard shall be had to the interest of all other banks. When the credit expansion began to cause alarm last spring, Congress amended the Act, granting to the Federal Reserve banks the right

put into effect a progressive discount rate in accordance with which a basic line of credit for a particular bank would be determined and any accommodation beyond this would be subject to a higher discount rate, which is subject to a progressive increase as the amount borrowed increases. Four of the Federal Reserve banks have applied the progressive rate, but its influence in checking expansion is problematical.

The Federal Reserve Bank of San Francisco has not adopted the progressive rate, but has required additional collateral, which serves to reduce the paper of the member bank eligible for re-discount with the Federal Reserve Bank and also to limit its borrowing capacity with other banks. The discount rates are determined by the boards of directors of the Federal Reserve banks, subject to the approval of the Federal Reserve Board.

The third fundamental principle is that of note-issue. Federal Reserve banks may issue Federal Reserve bank-notes and Federal Reserve notes. The former is a currency similar to National Bank notes in that it is based on bonds and has been used chiefly to supply bills of small denominations. The latter constitute a currency intended to expand and contract in volume as the volume of business expands and contracts—an elastic currency. Federal Reserve notes may be issued against gold, or against gold and re-discounted paper. They are in the custody of the Federal Reserve agent and are issued by him to the bank. Under normal circumstances there must be at least 40% of gold back of every Federal Reserve note issued, the rest being re-discounted paper; but this limit of 40% may be lowered by the Federal Reserve Board.

Those who have followed the reports of condition of the Federal Reserve banks will have seen that the average reserve of the system has been for months in the low forties and there has been much discussion of what would happen should it fall below that amount. As a matter of fact, the reserve of individual Federal Reserve banks has fallen far below 40%, but by the ability of Federal Reserve banks to re-discount for each other, banks having higher reserves come to the help of the banks faced with demands beyond their means, and in this manner the average reserve of the system has been maintained above 40%. But nothing would happen if the reserves of the system should fall below 40%, that is, nothing in the nature of bankruptcy of the system. The Federal Reserve Board would simply lower the required reserve percentage. There is nothing sacred about the 40%, and it is possible that much of the discussion about the dangerously low point reached has been welcomed by the Board as a valuable adjunct to its general campaign to impress upon the bankers and the public the extent of credit expansion and the need for curtailment.

The credit-lending power of the Federal Reserve banks lies in their power to issue Federal Reserve notes. A dollar in gold in the vault of a bank is worth a dollar and no more. By no possible means can the bank make it worth more, but in the vault of the Federal Reserve banks it is worth two dollars and a half in credit, or

Federal Reserve notes, if there is re-discounted paper in the hands of the bank.

Let us look at the transaction from another angle. John Smith is engaged in business and needs money to buy goods. He goes to his bank for a loan; his credit and his business are good, but his bank has reached the limit of its available funds, but if Smith's note is eligible for re-discount with the Federal Reserve bank, his bank, if a member, can make the loan for it, can immediately re-discount with the Federal Reserve bank and again be in funds. It gets from the Federal Reserve bank, Federal Reserve notes. John Smith's note may in this fashion be converted into currency up to 60% of its amount. John Smith's note would not circulate as currency but the Federal Reserve note will.

The ability of the Federal Reserve note currency to expand has been completely demonstrated, since there are now outstanding some \$3,000,000,000 of such currency. It has yet to be determined whether it has the ability to contract with equal facility as the volume of business contracts.

During the post-war period of readjustment, the Federal Reserve system has had many serious problems to face, but none more serious than that touching its policy toward inflation and high prices. With respect to the latter, the position has been consistently maintained that it was not the function of the system to attempt to regulate prices. Its duty pertained solely to dealing with the credit situation and if in its action in relation to credit, prices were affected, this must be regarded as incidental merely.

As long as a year ago the expansion of bank credit was a cause of concern to the Federal Reserve banks and to the Board, and in November 1919 the discount rates were raised. It was supposed that following the crop-moving season, liquidation would set in, credit would be contracted, and the reserves would be increased; but instead of liquidation, there was continued expansion, with the result that in January rates were again raised. The normal effect of a raise of rates is to discourage re-discounts and to cause the banks to restrict their loans, but the conditions of the early part of 1920 were not normal. There was a spirit of extravagance and of speculation; production had fallen off and distribution was seriously curtailed by deficient transportation; goods and farm products were stored in warehouses and terminals and could not be moved; they were being financed in large part on credit and until they could be moved to the point of distribution and consumption, these credits were 'frozen'. Moreover, it was a seller's market; the public was insistent upon buying and price seemed a small consideration. In these circumstances a raise in the discount rate could not have its normal effect. But the action of the Federal Reserve banks in raising rates and the warnings of the Federal Reserve Board that the credit situation was becoming acute, focussed the attention of the country upon the need of conserving credit. Through the Federal Reserve banks and the member banks the borrowing public was impressed with the necessity of

curtailing its loans and of limiting credit to the essential industries. In a remarkably short time the psychology of the general public underwent a marked change. It was no longer recklessly extravagant and regardless of price. The public demanded lower prices; it became a buyer's instead of a seller's market. Merchants reduced their stocks and liquidated a part of their indebtedness. The bankers sought to eliminate all unnecessary and speculative loans, transportation improved, and some 'frozen' credit was thawed out.

The fear in the spring had been that the seasonal demands of the crop-moving season could not be met without a reduction of the reserves of the Federal Reserve banks below 40%. That danger seems past. Liquidation has, in some directions, taken place, though the total volume of loans has increased; legitimate and necessary business has been financed; inflation has been checked without panic; price readjustments have been taking place. In the process some individuals and some industries have been hurt. There has been no market for wool; financing of the cotton crop, wheat, and the livestock industry has been difficult, but the policy of the Federal Reserve Board, aimed at the checking of expansion, and at the stabilizing of conditions to prevent a sudden crash, has met with marked success and approval.

Engineering Council

By E. H. LESLIE

A Department of Public Works of the Federal government as advocated by the Engineering Council of the National Engineering Societies was the subject of an interesting discussion at the recent meeting of the Council at Chicago.

For a great many years past it has been the practice of administrative offices to dump into the Department of Interior all matters of public welfare that did not fit in well with other branches of the Government. As a result the Department of Interior embodies so many different and unallied activities that efficiency and the best results have not been possible. The house-cleaning that is proposed is to establish a Department of Public Works, which will have within its scope all the engineering branches of the Government and, in a large measure, take on the present work of the Department of the Interior. It will, of course, have no relationship with Indian affairs, public health, and numerous other matters that at present come within the scope of the Department of the Interior. There has been considerable opposition to this movement on the part of the Army engineers by reason of the fact that such a department might supersede their present authority. It is hoped and expected that all the difficulties attendant upon the establishment of a Department of Public Works will be overcome, and new suggestions toward this end will be offered.

The report of the Patents committee was also of importance. It is hoped that the bill providing for increased pay to employees of the Patent Office will eventually pass Congress. There was a day when Government

departmental employees could exist on the governmental honorarium. However, that day is long past and a salary commensurate with the value of services rendered is very much in order, or the whole work of the Patent Office will be impeded. The work of this office is of real importance to engineers and the public at large, and as it has never functioned on a par with similar departments of some of the other nations, there is lots of room for improvement. To provide salaries for the employees, compatible with what similar services outside the Office would command, will be a step in the right direction and tend toward a stronger and more efficient organization. The Council is in favor of such a bill and is giving it the full support of the Societies.

The report of the License Committee was another important matter that came before the Council and was the subject of considerable discussion and diversity of opinion. There were those present who believed that if a referendum to the engineers was made on the subject, there would be a large majority opposed to a license bill. The majority of the members of the Council believed, however, that such would not be the case. It was generally agreed that a license bill for engineers is something that all engineers must anticipate whether they want it or not. Such bills are now in force in a number of the States and other countries and are almost inevitable for this country. It is, therefore, germane to the work of the Societies to take cognizance of this movement and give direction to it. If engineers are going to be licensed, it is well that, among themselves, a program or bill be worked out that will have their approval. Just what defines an engineer under the proposed license bill was a matter of discussion. The fact that the term has been so widely and so wrongfully used, makes definition important. There are men in charge of one horse-power gasoline engines who term themselves 'engineers' as well as men who design and take charge of important engineering projects. In the wording of the bill, the phrase "professional engineers hereinafter called engineers" was adopted. The proposed bill will apply to architects, engineers, and land-surveyors. The report of the Committee on the proposed bill was accepted. Edwin Ludlow voiced the opinion that a license bill would prove exceedingly awkward to the consulting mining engineers, as it would necessitate holding license in numerous States as well as countries. Philip N. Moore was of the opinion that a referendum to the mining engineers would show them not in favor of a license bill of any kind. J. Parke Channing differed with Mr. Moore in this, which seemed to be the consensus of opinion of the Council.

The work being done by the Council is of no little importance to the professions represented and it is to be hoped that the present organization can be continued as a permanent body and its field of activities enlarged upon. The numerous public problems having a direct bearing upon the engineer, require authoritative consideration at the hands of men qualified to speak and as such a representative Council is a real asset to the professions represented and a help to the Federal government.

Report of Special Gold Committee to the Secretary of the Treasury

February 11, 1919.

To the honorable the Secretary of the Treasury.

Sir: On November 2, 1918, your predecessor appointed the undersigned a committee to investigate present conditions in the gold-mining industry and to study the problem carefully and thoroughly with a view to definitely ascertaining all the difficulties confronting gold production and submitting suggestions of sane and sound methods of relief.

The nature of the problem submitted to the committee was well stated in the letter of Secretary McAdoo to Delegate Sulzer of Alaska, under date of June 10, 1918, to which reference has been made in almost all resolutions or discussions of the subject since that time. That letter is reproduced herewith.

At that time the War was at its height and there was very prospect of a prolonged war. Contrary to the belief apparently entertained in many quarters, the structure of banking credit in any country during war times does not depend very much, if at all, on the amount of gold that can be made available as a reserve for that structure. Undoubtedly the rise in prices in this country since 1914 is to a great extent due to the heavy importations of gold during 1915 and 1916, but it does not follow that the export of a corresponding amount of gold at the present time would operate to bring down prices. As a matter of fact, it is the judgment of this committee that it would not so operate until we have reached or approached normal peace conditions. In time of peace the gold reserve is undoubtedly an important factor in controlling the credit structure, but in time of war that structure is determined by other causes. This distinction is sometimes overlooked and much inaccurate thinking is due to this oversight. Under war conditions the imperative necessity of the Government for the production of war essentials determines Government expenditures, and this expenditure cannot be modified to meet the banking needs of the country; on the contrary, the banking policies of the country must conform to the fiscal policy of the Government. Under these circumstances, the only way in which the expansion of banking credits can be checked is by a reduction of civil demands to correspond with the expanding needs for Government expenditure. The credit saved through this reduction of civil demands becomes available to the Government through the purchase of Government securities, or through the payment of taxes. To the extent to which such saving and resulting investment does not take place, Government obligations must be taken by the banks, giving rise to credits to the Government which create additional purchasing power for the use of the Government. This additional purchasing power, in turn, com-

petes with the demands of private individuals, driving up prices against the Government and against the civil consumer and ultimately impairs the individual's purchasing power to an amount roughly equivalent to the impairment that might better have been brought about through voluntary saving. The credit structure thus erected depends inevitably upon Government needs and upon the willingness and ability of the community to impose upon itself voluntary restraint in expenditure. In other words, the structure will be high if the community fails to save.

The results in saving achieved in the United States were remarkable, but no program of saving can be instantly put into effect, and the expansion of the credit structure that took place under these circumstances was inevitable and could not have been controlled through any reduction in the gold reserve.

This being so and a long war being believed in prospect, it was important to maintain a strong gold reserve in order that there might be no impairment of confidence in the convertibility of our currency and in our ability ultimately to settle any international indebtedness in gold.

The cessation of hostilities has radically changed this situation, and, with the change in the situation, any need of particular effort to promote or stimulate our gold production which may have existed has ceased. There is now no danger of an impairment of confidence. The dimensions of our financial problems are becoming clear, and we know that we can without permanent strain meet any financial requirement the Government will be willing to assume. Some further expansion of credit may result from our expenditures for demobilization and readjustment, but we can look forward to a comparatively early contraction of our credit structure with the attending circumstances of a free gold market and a gold reserve that shall once more perform its normal function of regulating credit conditions. That movement will, we believe, be both preceded and accompanied by lower commodity prices.

Under these circumstances there is, in our opinion, no need for artificial stimulation of gold production. Not only has any need therefor passed, but there have come into operation causes that will in due time restore all industry, including the mining of gold, to a normal basis. Gold mining will then become again normally profitable and respond automatically to normal stimuli.

It is therefore the judgment of this committee that no steps should be taken by the Government to stimulate or promote the production of gold.

The representatives of the gold-mining interests very properly based their suggestions for relief on the public

necessity for a larger production of gold and not on the hardships suffered by them as parties interested in an industry in which the margin of profit had been turned into a loss. They recognized that such diminishing profits and such losses were inevitable under the shifting conditions of war, and that merely as producers they had no better claim to relief than any other section of the community suffering a reduction of profits or incurring losses under the changing incidence of war conditions.

In the course of its consideration of the subject referred to it this committee has conferred with a committee appointed by the American Gold Conference held at Reno in August 1918, under the presidency of Gov. Emmet D. Boyle, of Nevada; it has had the benefit of the very complete survey of the conditions of the gold-mining industry contained in the report dated October 30, 1918, of the committee appointed by the Secretary of the Interior to study the gold situation, of which Hennen Jennings, Esq., was chairman, and of the report dated November 29, 1918, of the gold production committee appointed by the commissioners of the British treasury under the chairmanship of Lord Inchcape; they have conferred with or secured the views of Prof. Irving Fisher and other eminent economists, besides which they have had referred to them a considerable volume of correspondence expressing widely varying views which had been received by the Secretary of the Treasury and the Director of the Mint.

It is interesting to note that the British treasury committee arrived at the same conclusion as that which we have reached.

We can not refrain from expressing gratification at the substantial unanimity of opinion among those whose position or experience entitled their views to respectful consideration against suggested measures of relief that would have had a tendency to undermine or upset our standards of value.

Respectfully submitted.

Oil-Pipe Lines

*The pipes for conveying oil are laid on the surface of the ground, or at a depth varying from 18 in. to 3 ft. beneath the surface, and the main lines are generally 8 in. diameter. The oil is forced through the pipes by means of pumps operated either by steam or by internal-combustion engines. The pump stations are situated from $1\frac{1}{2}$ to 90 miles apart, varying with the condition of the country through which the pipe-lines extend, and the viscosity of the oil to be handled. As stated, the size of pipe generally used is 8 in. diameter. The specifications require that it be of a uniform quality, and of steel, that the threads be carefully made so as to make as perfect a

union between joints as possible, and that it be capable of safely withstanding an internal pressure of 2000 lb. per square inch. It is estimated by the U. S. Geological Survey that the total mileage of oil trunk lines in the United States today is approximately 34,000, and that the gathering systems, which are a fundamental part of the trunk systems, aggregate about 11,500 miles in length, making a total of 45,500 miles. At the time most of the lines were constructed, the average cost per mile based on 8-in. pipe was about \$6500. The cost of the average pump station at that time varied from \$130,000 to \$250,000. The cost at the present time would be much in excess of these figures on account of the increased cost of equipment and the labor of installing.

The difference between the published pipe-line tariff rates and the railroad rates for shipping crude oil have always been so large that refiners and producers, even though they have no pipe-line systems of their own, can not afford to ship by rail, except for comparatively short distances. The pipe-line rates, although greatly increased in recent years, are still much lower than those charged by the railroads for tank-car shipments. It is evident, therefore, that because of this relative cheapness in transportation, so long as the oil industry endures the pipe-line systems of the country will be a very important adjunct to it.

The viscosity of the oil to be transported, and the topography of the country through which pipe-lines pass are the governing factors determining the distance between pumping-stations. The average distance between pumping-stations in the Midwestern and Eastern States is about 35 miles, while the average distance between stations in California, where a relatively thick viscous oil is handled, is about 12 miles, although, as pointed out above, stations are sometimes not more than a mile and a half apart, and in extreme cases are placed as much as 90 miles apart. The equipment of a pumping-station depends primarily upon the quality and quantity of the oil to be handled. It depends also, to a certain extent upon the fuel and water supply. Equipment is usually provided in excess of ordinary demands, so that there is always in reserve extra pump-power to meet unusual demands, thereby avoiding shut-downs where repairs are needed to pumps and boilers. As has been pointed out the usual form of motive power are steam-engines and internal-combustion engines. The pumps are designed to deliver through an 8-in. pipe-line approximately 30,000 bbl. of oil in 24 hours, working under a line pressure of 700 to 900 lb. per square inch.

THE AVERAGE MONTHLY production of copper in Mexico has reached 4,681,020 lb., according to reports of the Department of Industry, Commerce, and Labor of the country. The average monthly production of gold, according to the same authority, is now 1965 oz. and silver 170,824 oz. At the present time there are in Mexico 60,569 denounced mining claims, 2017 of which were denounced prior to 1892. Taxes are being paid on 30,990 claims, while 3867 claims are reported as being actively worked.

*Abstracted from a bulletin of the U. S. Bureau of Mines by C. P. Bowie.

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

BISBEE MINES ARE CURTAILING FURTHER.—MINERS ARE LAID-OFF.

BISBEE.—The Denn-Arizona Mining Co. ceased operations on October 30, except for pumping, and laid-off approximately 100 men; this action being taken on account of the condition of the copper market. The Shattuck-Arizona company and the Shattuck mill, which are under the same management, will continue to operate for the time being at least, on the same basis as heretofore. This announcement, in conjunction with that of the curtailment of work on Sacramento hill, by the Phelps Dodge interests, causing a lay-off of about 350 men on November 1, comes as a decided blow to the district. That it is a temporary condition that will change as soon as there is an improvement in the copper market, is agreed generally among local mining men.

The crisis in the copper market is only temporary, according to G. H. Dowell, general manager of the Copper Queen branch of the Phelps Dodge Corporation at Bisbee. "The Copper Queen has at this time more than seven months production on hand," said Dowell, "which aggregates about 35,000,000 lb. of copper. Wages and supplies have been high and it has cost about 18c. per pound to produce the copper. The present prices of copper are in my mind artificial. They have not been governed by the law of supply and demand." Mr. Dowell said that it is impossible to close down, but that operations must be curtailed to a minimum—probably less than 50% of normal. He declared that with the present cost of supplies and wages, and the present price of copper, it is impossible to operate at a profit. With an improvement in the situation Dowell said that the company plans the expenditure of three or four million dollars on its reduction works at Douglas. Experiments with this in view have been carried on there by H. H. Stout.

JEROME.—The United Verde Mining Co. of Jerome laid-off 30% of its men on November 1. H. Dewitt Smith, superintendent of mines, said: "Our action in laying off practically one-third of our men, is due simply to the fact that we cannot sell our copper. No men with dependent families are being laid-off. We are laying-off only single men, or men whose families are not living with them in Jerome. I should say that about 75% of our single men will be laid-off." The United Verde Extension Mining Co. has declared a quarterly dividend of 50c. per share, payable November 1, to stockholders of record at the close of business October 5. A statement to stockholders by the

board of directors is as follows: Development work on the lower levels has been slow, but on the 1500-ft. level a notable increase of higher-grade ore has resulted. On the 1600-ft. level we have drifted in ore for 100 ft., but the indications for as large a body of ore as we have on the 1500-ft. level are not so good. The 1700-ft. development in favorable ground will be delayed until further work is done on the 1600-ft. level. In the upper levels of the

KINGMAN-OATMAN DISTRICT, ARIZONA

mine development has been satisfactory. The following figures are from the financial statement:

Cash on hand October 1, 1920.....	\$1,069,442
Liberty bonds, par value \$3,364,400, market....	2,946,581
Copper on hand October 1, 1920, pounds.....	27,014,614

WICKENBURG.—The advertisement for sale at sacrifice prices, by a Los Angeles firm of the entire equipment of the famous Vulture mine at Wickenburg, recalls the fact that for many years this mine was one of the best producing gold properties in Arizona. It is reported that several million dollars worth of ore was removed from this property. The mine was shut-down about three

years ago and it was recently decided to sell the equipment while it was in good condition. This is said to be worth considerably over a quarter of a million dollars and to include modern equipment of all kinds.

CAVE CREEK.—The old Go John mine in the Cave Creek district, 30 miles north of Phoenix, is again shipping ore after years of inaction. Samples from the face of new workings show nearly 30 oz. silver, 0.5 oz. gold, and some copper. A long tunnel is being run to cut the vein from which the rich ore is being taken at a depth of 50 feet.

OATMAN DISTRICT.—A shoot of \$24 ore is reported in the United American mine at Oatman. Following the recent discoveries in the Tom Reed, this strike is of particular interest to the Oatman district.

GLOBE.—The Old Dominion company has announced that four contests for prizes in first-aid work, open to all employees, will be held on or about December 1, 1920, February 1, April 1, and June 1, 1921. Three teams of six men each must take part in the contests, and the prizes will be in the form of a payment of \$5 per month to each member of the winning team for the number of months remaining in the year from date of contest. The contests will be held under the auspices of the Globe-Miami Mine Rescue and First Aid Association.

SUPERIOR.—In a drilling contest held recently an American mine-drilling team won a victory over a Mexican team in a 15-minute contest, winning a prize of \$1000. The winners drilled 36½ inches in the 15-minute period, as compared to 24½ in. by the Mexicans. Dropping of a hammer, however, badly handicapped the latter team.

COLORADO

GAUSCHE PROCESS IN SUCCESSFUL OPERATION.—LESSEES AT LEADVILLE ARE ACTIVE.

CRIPPLE CREEK.—The new mill and concentrating plant of the Lincoln Mines & Reduction Co. on Ironclad hill, using the Gausche process, is in operation, and reported to be handling 100 tons of low-grade gold ore from the company's property daily. The initial run and clean-up will be of interest to local operators. Miners are steadily returning and operating forces are steadily getting back to normal.

October production, curtailed by the labor shortage in the first half of the month, totaled 35,256 tons with an average value of \$12 per ton and gross bullion value of \$425,298. The Golden Cycle mill at Colorado Springs reported the treatment of 16,000 tons of \$19 ore and the Portland company's Independence mill handled 18,556 tons of \$3.70 grade. The remaining 790 tons shipped direct to the smelter at Pueblo had an estimated value of \$75 per ton.

IDAHO SPRINGS.—The holdings of the Argo Reduction & Ore Purchasing Co., including the old Gunnel mine and the Argo mill and tunnel, have been taken over by the Gem Mining Co. This company recently acquired the properties of the Idaho Mining, Tunnel & Transportation

Co. which it is operating. The Gem stockholders are New York capitalists.

DURANGO.—The Co-operative Mining & Milling Co., owning and operating properties in the La Platas, has recently made the discovery of a four-foot vein of good silver-gold shipping ore. Lessees at the Idaho mine are reported mining \$50 ore and have a shipment out; May-day lessees are cleaning out No. 2 tunnel preparatory to development. Heavy snow has fallen.

LEADVILLE.—Lessees of the Fanny Rawlins have opened a new body of zinc sulphate at the first level and have commenced production at the rate of one car per week. This ore is shipped to the Western Zinc Co.'s plant at Leadville. Sub-lessees on the third and fourth levels are mining and shipping silver ore averaging \$50 per ton at the rate of 50 tons weekly to the A. V. smelter. The ore also carries some gold and copper. The Helen Gould mine in Tennessee gulch is producing low-grade gold-silver-copper ore. The mine is operated under lease. The National Mining Co., operating the Chicago in Iowa gulch, has cut minor veins in the course of development but is continuing its tunnel to a point 200 ft. ahead where a junction of veins is looked for, and where it is expected an orebody of good size will be found.

MICHIGAN

MOHAWK.—ARCADIAN CONSOLIDATED.—SENECA.

CALUMET.—With some producing properties in the Lake district closed and others operating far below the rate of 1918, surplus metal stocks are steadily growing and the mines can do little else than mark time. With the recent drop in metal prices, the Lake mines are in a position not unlike that which prevailed at the beginning of 1919 when copper dropped from 26 to 14½¢ per pound. Efforts have centred throughout the 'lean months' on a reduction in costs and there are hopes that the mines will be able to survive the dull condition of the metal market.

Ahmeek's production is holding close to that of September, with an average of 2750 tons of 'rock' daily. The October yield is estimated at about 1,600,000 lb. No. 2 shaft continues to be the biggest producer. The fissure vein in this shaft still plays an important rôle and considerable 'mass' copper is coming from the fissure drifts. The openings are going westward on seven levels and, in the event mineralization continues, all of the drifts will reach the Kearsarge conglomerate, which is about 1250 ft. west of the Kearsarge amygdaloid. From time to time some of the drifts widen out to two feet, making the operations highly profitable. The fissure openings will permit the first extensive exploration of the conglomerate formation since it was opened by the old Ahmeek.

The Kearsarge lode on the 25th level of No. 4 shaft, Mohawk, has begun to widen and there are indications it again will reach the abnormal width of 35 or 40 ft. The continuation of this 'wide spot' is a decidedly favorable factor in Mohawk's life. In addition to increasing the yield per ton it is adding more years to its period of

productiveness. The same characteristics that were noted in the 22nd, 23rd, and 24th levels are visible in the 25th and it is believed the wide section will continue at least for 400 ft. just as it has in the levels immediately above. Operations continue in the levels between the 22nd and 24th, inclusive, and the ground is being removed as close to the hanging wall as possible, leaving only sufficient ground to ensure safety and prevent caving. The workings also are kept reasonably safe by the use of poor 'rock' from the upper levels for filling purposes. The yield of Mohawk varies from 23 to 24 lb., or slightly above the normal for the past six months, and 'mass' totals about 7% of the entire production in refined copper. Mohawk and Wolverine continue to mill their rock in the Mohawk plant and this arrangement will continue as long as the lull in the market holds out and the price of fuel and labor remains at present levels. Both mines will have a sufficient supply of coal until the re-opening of navigation in the spring, providing operations continue on the present basis of 60% of normal. The prevailing price of bituminous coal, \$11 per ton delivered at the mine, makes it improbable that any of the Lake properties will lay in stocks to provide for a possible increase in the metal demand. Most of the companies, in fact, consider themselves fortunate to secure enough coal for the winter on the curtailed basis. Mohawk is constructing a number of stope-scraper, modeled on the lines of one in service for 60 days. Mohawk also is building a level-scraper, patterned after its zinc-field model. Less steel will be used in its construction, however, making it possible to move it from level to level with greater facility.

Franklin's future course, so far as resumption of operations is concerned, will not be announced until December 1, though a decision was expected at the end of October. Pumps in No. 1 shaft will continue in commission so that the mine will be dry and ready to re-open on short notice. A small force of men has been kept at work since suspension, and the openings are in condition for immediate use, providing instructions to resume are forthcoming.

Arcadian Consolidated will cut the 7th level in its New Baltic shaft shortly and by the time the vein is opened by drifting a decision will have been reached as to winter plans. In the event the management decides to continue operations through the winter, the immediate objective will be the 9th level. At the rate the shaft has been sunk from the 4th, the 900-ft. station should be cut during late winter or early spring. The principal operation thereafter—the driving of a drift to connect with the Arcadian shaft—will be one of great importance to the property, for it will determine the extent southward of mineralization. Inasmuch as the showing in the Arcadian shaft is satisfactory there is hope for the extension of the rich ore opened in the Baltic shaft. This would ensure long levels of commercial 'rock' that could

be tapped from both ends, making possible a large production.

In connection with the sharp rise in Seneca stock there have been rumors of the finding of a new lode. There is no confirmation. The only manner in which a new vein would be opened would be by cross-cutting, and for the past year or more, save for diamond-drill operations, Seneca's work has consisted entirely of developing the Kearsarge amygdaloid. Among reports that have been circulated is a story that the Douglass lode has been opened on Seneca property. Little credence is given this rumor, for the Douglass vein, which incidentally has been opened only on the old Arcadian property, is situated far to the east of the Kearsarge amygdaloid and nearer the zone explored by Mayflower. It is not impossible that the Douglass could be tapped by Seneca,

FAGAN CONSOLIDATED MINE, SIMON DISTRICT, NEVADA

at great depth. The showing in development work continues satisfactory.

NEVADA

J. H. FARRELL REPORTS ON THE DIVIDE MINE.—ORE-RESERVES ARE \$1,500,000 WITH ONLY FAIR PROSPECTS FOR FUTURE DEVELOPMENT.

DIVIDE.—In his report submitted July 1, 1919, A. I. D'Arcy, then consulting engineer to the Tonopah Divide company, said that "as a matter of speculation," figuring silver at \$1 per ounce, the mine "could be expected to produce \$9,108,000 gross from the present workings." On December 31, 1919, E. A. Julian, then consulting engineer, made a report that was not made public until nearly four months later. Julian, figuring silver at \$1.25 per ounce, estimated the gross value of the ore at \$1,385,000. Now J. H. Farrell, reported to have examined the mine for the Hayden-Stone-Jackling interests, says in his report that the "assured and probable ore" is worth \$1,558,733, figuring silver at \$1 per ounce. "New ore opened in recent development work is, of course, only partly blocked-out, but liberal allowance has been made, both as to continuity of shoots and average value of the ore", the report says. The D'Arcy report was optimistic

as to the future of the mine, the Julian report was less so, and the Farrell report is still less so. D'Arcy said: "The appearance and size of the vein surely indicate that the orebodies will persist to great depth", whereas Farrell says: "Oxidation, kaolinization, and leaching have extended from the surface to the 1000-ft. level, but primary sulphides have been left in most of the ore-shoots as close to the surface as the 165-ft. level. When the water-level is as deep as it is here it is often not well-defined and does not produce a distinct zone of enrichment. Under such circumstances, while metals are re-distributed to a considerable extent, they are not necessarily concentrated. Another consideration is that an important part of the original silver content of the upper vein-zone has been stabilized as the relatively insoluble silver chloride." However, he says: "There is always the mining chance that the rather weak primary mineralization of the upper levels may, as its source is approached, give place to a much more important occurrence of ore minerals, and this chance is worth investigating, not only on the 1000-ft. level, but possibly at greater depth, though this will depend largely on the condition on this level." He considers that "good ore occurring at or near the water-level, due to metals leached from the upper or oxidized zone", is a "possibility". But, he says: "Owing to the rather erratic character of the fractures and the fact that they developed into clay seams rather than open fissures, the primary mineralization probably was correspondingly spotty or erratic, as was also the concentration due to downward-leaching surficial waters. It is accordingly impossible to determine with any certainty whether the apparent weakness of the primary stage is due to structural conditions unfavorable to ore deposition or to a brief and ineffectual period of mineralization. The bulk of the evidence rather favors the latter hypothesis. This point is important; otherwise the deposits might be expected to become more extensive with depth and more concentrated, especially if a favorable formation underlies the Divide breccia." Farrell makes several statements regarding the possibility of secondary enrichment and in the most definite he says in referring to a report made by George H. Garrey: "The writer has read this report and has derived much valuable information from it, though, differing with Mr. Garrey, he believes that secondary enrichment will be of minor importance." Two ore-shoots have been mined for widths of 8 to 30 and lengths of 50 to 75 ft., according to the report. "The more important parts of these shoots are above the fourth level. The orebodies occur at intersections of cross-fractures with the main vein-zone and other smaller shoots doubtless will be found within the developed parts of the vein. It is thought that important additions to the ore-reserves will be made by prospecting now being done above the 165-ft., or first level. The showing on the fourth and fifth levels is rather disappointing, but there are still some development chances to be tried." D'Arcy reported of the fourth level that the south-east drift, for 110 ft., "sampled across the width of the drift at 5-ft. intervals, give average assay values of

\$148 per ton." The report is regarded as definitely settling the uncertainty that followed the issuance of the Julian report, which it checks closely as to ore-reserves. Noting the work being done on the 800 and 1000-ft. levels, Farrell says: "The early results of this work may not fulfill expectations, but there is a chance of finding by consistent development orebodies similar to those of the upper levels, but possibly not of such high grade, as the upper ores are formed by silver-chloride enrichment. However, the prospecting chance on the 1000-ft. level, as well as below water-level, is one that should be thoroughly tried out." Practically all of the ore in the mine is in the rhyolite breccia and the report points to the possibility of finding gold ore in the rhyolite. Farrell says of this: "Earlier mining operations proved the existence of several small veins in the rhyolite and later work in the same formation has suggested the possibility of extensive low-grade deposits. The possibility is worthy of detailed investigation."

GOODSPRINGS.—The Christmas Consolidated is to spend \$4000 in development of the seven vanadium claims owned by the company. Another \$1000 will be spent in building roads and sinking a shaft a short distance to find water. Little work has been done on the claims.

WEST DIVIDE.—Zeb Kendall has completed payments on the McCoy and Cook stock in the West Divide that he held under option. A cross-cut has been driven to the vein 25 ft. below the tunnel-level and 3½ to 4 ft. of "rich ore" has been found, according to L. L. Patrick, manager.

BATTLE MOUNTAIN.—The 400-ft. shaft of the Betty O'Neal, an old silver producer at Lewis, 12 miles south of here, has been unwatered and the first mining since 1883 has been started, with 20 men employed. The water had been at the 250-ft. level for 38 years, but the shaft-timbers were found in good condition. It is said that several good widths of ore have been found and Noble Getchell, general manager, whose father worked the mine until 1883, plans to build a mill in the spring.

MINA.—It is reported that engineers of the Dome Mines, Ltd., have been retained to supervise the construction of the reduction plant of the Simon Silver-Lead Co. and are now at the property. The capacity of the initial unit is to be 150 tons per 24 hours, constructed so that additional units may be added. The milling ore developed in the mine to date together with the additional tonnage exposed as development work is carried forward on the lower levels is sufficient to keep the mill in operation for several years.

PIOCHE.—John R. Cook, manager for the Mascot Silver Mining Co., which owns the Yuba East mine, near here, is at Salt Lake City making arrangements for the early resumption of work at the property. A large tonnage of milling ore is available for treatment. About two years ago, several cars of high-grade silver-lead ore were shipped from the property, since which time it has been idle. The Salt Lake Route has taken no action as yet regarding a reduction in freight-rates on shipments of ore from this district. During the week ending October 30, the

Prince Consolidated shipped 1750 tons; Virginia-Louise, 650; Consolidated Nevada-Utah, 200; Bristol Silver Mines, 160; Black Metals, 105; Bristol-Battles lease, 45; Campbell lease, 45; total, 2955 tons.

UTAH

BRONZE TABLET FOR UTAH COPPER EX-SERVICE MEN.—
REPORT OF PROGRESS AT TINTIC STANDARD MINE.

SALT LAKE CITY.—On November 3 a magnificent bronze tablet, the gift of the Utah Copper Co. and the Bingham & Garfield Railway Co., was dedicated in the office of R. C. Gemmell, general manager, in the presence of the Salt Lake City office employees of the two companies. The dedication address was by Reverend Elmer I. Goshen. The tablet bears the inscription at the top "This tablet is Dedicated in Honor of Those Employees Who Answered the Call of Our Country and Enrolled for Service, 1917-1918" followed by the names of the employees. About 775 employees of the two companies entered Government service during the world war, 17 of whom made the supreme sacrifice.

The Grasselli Chemical Co., which has been in the zinc-ore purchasing business in this State for twenty years, has decided to close its offices in this city. George H. Short, local manager, states that this action has been taken on account of the increase in freight-rates, as well as the unsatisfactory market conditions. The hearing before representatives of the Interstate Commerce Commission regarding increases in intrastate freight-rates on ore and coal was begun on November 1. Walter Fitch, president of the Chief Consolidated Mining Co., the largest shipper in the Tintic district and one of the leading silver producers in the United States, introduced exhibits to show the high earning power of the railroads on existing rates on ores. He stated that they must be the source of substantial profit to the railroads, and characterized the plea of the carriers as "a blind business proposition". Jackson McChrystal, representing the Gemini, Godiva, Ridge & Valley, and Eureka Mines companies, introduced testimony to show the effect the proposed increase in rates would have on the properties he represented. A. G. Mackenzie, secretary of the Utah Chapter of the American Mining Congress, and H. W. Prickett, of the Traffic Service Bureau, gave their views on the proposed increases, and expressed the opinion that many of the low-grade metal and coal mines of the State would be compelled to suspend operations.

BINGHAM.—The contract labor system at the Utah-Apex property, under which miners and other laborers are paid according to the amount of work accomplished, is resulting in an increased efficiency of 50% over the wage-scale system. Sinking of the four-compartment shaft from the 2000-ft. level to the 2400 is proceeding satisfactorily, although somewhat handicapped by shortage of labor. It is expected that an extension of the rich

orebody cut on the 2000-ft. level will be opened at this depth. On the 1300 and 1400-ft. levels, where the downward extension of the Parvenu orebody—one of the richest deposits in the property—has been found, conditions are interesting. About 300 tons of ore per day is being treated in the mill, where an oil-flotation unit was recently installed with excellent results. From 200 to 300 tons per day of straight smelting ore is also being produced. When the condition of the market for lead warrants, production can be substantially increased. No action has been taken as yet by the Utah Consolidated Mining Co. to appeal the decision of Judge Johnson in the recent litigation to the Circuit Court of Appeals. Within 30 days after the official entry of the decree, the Utah Consolidated must file with the court a statement of all ore extracted from ground now held to belong to the Utah-Apex Co. The latter then has the right to take exceptions to the findings. Since the court's decision, the

THE ROCHESTER MILL, AT ROCHESTER, NEVADA

Utah Consolidated has ceased mining in the workings wherein it was found to be trespassing.

A special meeting of the stockholders of the Bingham Mines Co. was held at the head office of the company in Portland, Maine, on November 10, to vote on recommendations of directors that the company purchase 50,000 shares of its stock at \$10 per share and hold same as unissued capital stock, thereby reducing the outstanding capital from \$1,500,000 to \$1,000,000.

EUREKA.—The directors of the North Standard Mining Co. have levied an assessment of one cent per share on the outstanding stock. The levy was delinquent November 2 and the sales-date is November 22. Shipments of ore from this district for the week ending October 30 dropped back to the normal output, totaling 129 cars, of which the Chief Consolidated shipped 35; Tintic Standard, 34; Dragon, 12; Mammoth, 11; Eagle & Blue Bell, 7; Iron King, 6; Grand Central, 6; Victoria, 4; Swansea, 3; Iron Blossom, 3; Sunbeam, 3; Bullion-Beck, 2; Ridge & Valley, 1; Gold Chain, 1; Alaska, 1. The power-line to the South Standard property has been completed and the

transformers installed. It is stated that the shaft at this property will be sunk to a depth of several hundred feet during the winter. Work has been suspended at the Copper Leaf property, in the eastern part of the district. During the past few years, considerable exploration work has been done by this company in the hope of finding an extension of the Tintic Standard orebody. A deep working shaft was sunk and extensive drifting has been done on two levels. Many small bunches of ore were found but no large deposits. The property is well equipped, amply financed, and it is not expected that it will remain inactive for any considerable period.

During the month of October, the Tintic Standard Mining Co. shipped 150 carloads of ore, containing 50 to 55 tons per car, which netted the company from \$25 to \$30 per ton, or a total net profit of approximately \$200,000. Shipments could be increased if the railway company could supply additional cars. The present production is coming from the 1100, 1250, and 1350-ft. levels. The reserves of mill-ore are estimated at between 700,000 and 800,000 tons, with additional tonnage being developed all the time. More miners have been secured and the employees as a whole are rendering more efficient service, according to E. J. Raddatz, president. The area in which operations are being conducted constitutes about 600 or 700 ft. on the strike of the mineralized zone, which runs through the property for a distance of nearly three miles. Mr. Raddatz believes it will take five years to open the mine to permit maximum production.

PARK CITY.—One of the most important pieces of development work now under way is the driving of a drift from the 600-ft. level of the Ontario to prospect at depth the Naildriver property. This drift will enter the latter property at a depth of 2300 ft., or 400 ft. below the deepest workings at present, and will also serve to prospect virgin territory of the Ontario. The Judge Mining & Smelting Co. is retaining its technical staff at the zinc smelter, which was closed on October 22, for the purpose of conducting experiments and to have the plant in condition for resumption of operations when conditions warrant. Practically all of the workmen at the smelter have been given employment in the mines of the district.

BRITISH COLUMBIA

ENGINEER MINE INVOLVED IN LEGAL CONTROVERSY.—PLATINUM IN TULAMEEN RIVER COUNTRY.

VANCOUVER.—The Federal government has instructed the Royal Canadian Mounted Police to turn back prospectors going to Fort Norman, at the junction of the Great Bear and Mackenzie rivers, unless they are completely equipped to withstand the rigors of the northern winter. This order is similar to one in effect during the rush to the Yukon, when gold was first discovered, and, like that one, has been issued purely to prevent useless loss of life and privation among unequipped people rushing to the northern regions to stake claims. A number of properly equipped parties have arranged to make the trip within the next few weeks. By a decision recently

handed down by the Supreme Court, Chief Justice Hunter has dismissed the action of Stewart et al v. the Molybdenum Mining & Reduction Co., Ltd. The case has been dragging through the courts for some time. It involved the title to the Conundrum claim, at Alice Arm, on which both silver and molybdenum have been developed in commercial quantities. The amendment to the Semi-monthly Payment of Wages Act, passed at the last session of the local legislature and providing for 26 pay-days annually, each falling on a Saturday, has become effective. The new law affects the coal mines, but not the lumber and fishing industries, to which the original act also applied.

The suits predicted with reference to the Engineer mine, at Atlin, one of the best known gold properties in the Province, are before the courts. W. L. Goodwin and eleven other prospectors have taken out a *lis pendens* to prevent the sale of the property until their claims can be brought before a grand jury. It is suggested that a sale for \$3,000,000 to Cobalt interests is in negotiation. Mr. Goodwin and his associates assert that they, and not the estate of the late Captain Alexander, are the lawful owners of the mine. Twenty years ago, it is declared, they staked the claims now known as the Engineer group and Capt. Alexander, it is alleged, staked over them, altering the lines and making the eleven claims which afterward were known as the Engineer claims. It is claimed that their property was fraudulently 'jumped' and recorded, and that crown grants were wrongfully issued to the Alexander party. The second action against the Alexander estate is brought by W. Pollard Grant, of Vancouver, who claims a one-fifth interest in the mine and affirms that documents in his possession will prove that Capt. Alexander was his trustee for the one-fifth interest in the mine.

The Canadian Advisory Council for Scientific and Industrial Research has made an appropriation to finance experiments in the treatment of the silver-lead-zinc ores of British Columbia. Horace Freeman, chemical and metallurgical engineer, and secretary of the British Columbia branch of the Council, states that the grant is sufficient to cover the first twelve months work. Mr. Freeman will begin his research immediately and is hopeful of finding an economic method for the handling of the complex sulphide ores. Mr. Freeman is responsible for a formula, now in use at Niagara Falls, for the making of cyanide from atmospheric nitrogen. The product is in use in gold and silver milling plants in the United States and Canada.

HAZELTON.—J. D. Galloway, resident mining engineer for the district, recently visited the Babine Bonanza, and reports an excellent showing of ore where the tunnel cut the orebody. Several directors from Spokane also visited the property, and as a result of their visit it has been decided to use hand-steel to drift on the lode rather than wait for the erection of machinery. This change of plan has been reached because of the bad state of the roads, after the continuous rains. They are in places little bet-

ter than quagmires, and the passage of heavy machinery over them is impossible.

ARROW LAKES.—The Millie Mack mine, near Burton, has 50 tons of high-grade awaiting the raw-hiding season to get it to the road. The Millie Mack was located more than 20 years ago by George McDonald. It has changed hands several times, and at present is owned and operated by H. E. Foster. The ore carries both gold and silver, the latter predominating.

GRAND FORKS.—The diamond-drilling at the Franklin Camp, which was being done under the supervision of Philip B. Freeland for the Provincial government, has been stopped for the season, the contractor realizing that he could not continue operation profitably through the winter. A total of 2888 ft. has been drilled during the season, most of the work having been done on the Gloucester claim.

PRINCETON.—H. R. Van Wagenen, general manager for the Canada Copper Corporation, recently made the following announcement with regard to the starting of operations at Copper Mountain and at Allenby: "Only the first 1000-ton unit is in operation, nor is it as yet up to capacity, but the tonnage treated is constantly being increased. The recovery at the mill has been satisfactory right from the beginning. Power from the West Kootenay Power Co. was made available at the mine on October 17; the first train of 10 cars over the Copper Mountain branch of the Kettle Valley railway was moved from the mine to the mill on October 19."

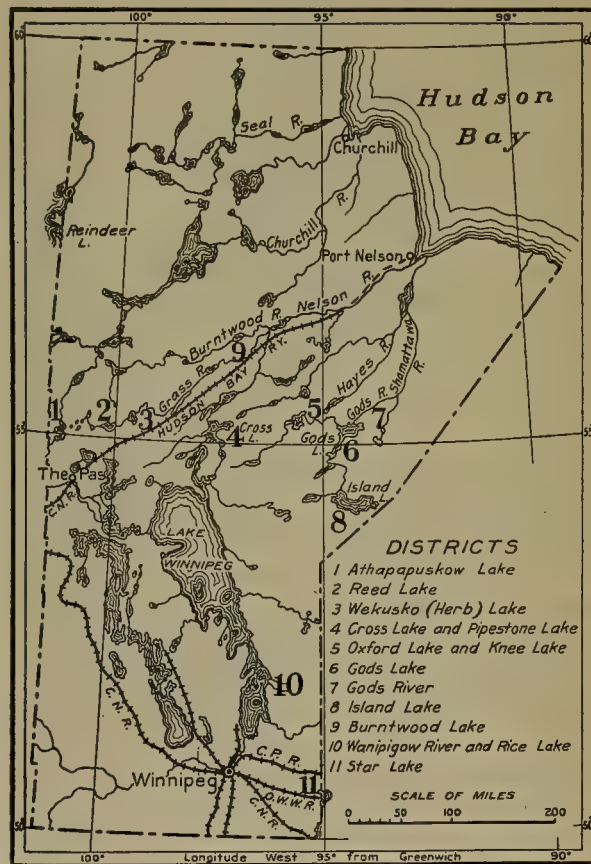

That a vein of platinum, 4 in. wide and 30 ft. long, in a 7-ft. lode of serpentine rock, exists near the headwaters of the Tulameen river, is the assertion of Robert Stevenson, a pioneer prospector, who is one of the few still living who took part in the gold stampede of the '60's into the Cariboo. This find was made, Mr. Stevenson states, in 1877 and ever since he has kept the claim alive. With platinum at 50c. per ounce he did not pay special attention to the development of the property. He has taken a force of men with him to open the vein, which he expects to be profitable with platinum selling at \$100 per ounce.

MANITOBA

THE FLIN FLON PROPERTY.—RICE LAKE DISTRICT.

THE PAS.—Five years ago four prospectors discovered indications of copper at a point some 60 miles northwest of The Pas and staked numerous claims. Today this deposit is known at the Flin Flon and 16,000,000 tons of a mixed sulphide ore, valued at \$9.50 per ton, has been proved above a depth of 900 ft. The property is at present under option to New York and Toronto capitalists, the price being given at \$3,000,000. Diamond-drill holes were put down 900 ft., at which depth the ore-body was showing no sign of becoming leaner. Now, this last summer, a large force of workmen has been busy sinking shafts and drifting. Two shafts, 400 ft. apart, have been sunk 200 ft., and are being connected by a drift, which should be completed by January. At present 150 men are employed, although the force would have

been larger had laborers been obtainable. The Flin Flon property is on the border line of the Province, in fact several of the claims are in Saskatchewan, and to reach it a railway 85 miles long must be built. This the Federal and Provincial governments seem inclined to do, providing guarantees are given by those operating the property that a certain tonnage will be smelted. It is estimated that to develop the property to a producing point, build the smelter, and harness the water-power now running to waste on the Sturgeon river will cost not less

than \$5,000,000. The ore is a mixture of copper, iron, and zinc sulphides, containing some gold.

It is reported that the Bingo Mines company has completed the sinking of its shaft to the 50-ft. level. Another contract has been let to continue the shaft to 200 ft. and also to cross-cut at the 100-ft. level. The object of the cross-cutting is to determine the value of the four veins which appear on the surface, all of which are within 60 ft. of the main vein. Sampling in the shaft gives returns ranging from \$23.60 to more than \$100.

RICE LAKE.—This district, which lies on the east side of Lake Winnipeg and within 100 miles of the city of Winnipeg, is passing through a crisis. The public has lost interest in the field, owing to the reputation it earned for being more renowned for samples than for steady production, but it is probable that better times are in

store for it. Many competent judges believe that there is more than one property that would make a mine if given a fair chance. Unfortunately the number of experienced prospectors is small, snow-stakings many, and capital scarce. Many heard with regret that the Gabriel had proved disappointing under the careful sampling of J. B. Tyrrell; but the directors would probably have a following in subsequent work, as it is recognized they acted for the best interests of all concerned when they decided to suspend operations and accept personal losses.

ONTARIO

MINERS ARRIVE FROM CORNWALL.—PATENTED CLAIMS ARE FORFEITED FOR DELINQUENT TAXES.

COBALT.—Cornish miners are beginning to arrive in Northern Ontario, seeking employment in the gold and silver mines. They have been imported on account of a shortage of labor, and have been assured steady employment at wages above the rate in England. Close to two hundred have already crossed the Atlantic, and more will follow. An exceptionally dry season has caused low water in the rivers and has left the mines short of hydro-electric power. As a consequence, the silver mines of Cobalt were obliged to work at considerably reduced capacity during the last half of October. Fall rains are now starting and the next few weeks is expected to bring relief. The Ontario Department of Mines passed an Order-in-Council on October 13 declaring all patented mining claims forfeited and open for re-staking, on and after noon of October 28, on which the owners have failed to pay a certain Provincial mining tax of five cents per acre. Various property owners, including the Teck-Hughes, Hudson-Kirkland, and Ontario Solid Silver mines appear to have been unaware of such a tax and were included in the list of delinquents. By special Orders-in-Council the Government has since recalled these properties from forfeiture, but has not taken action in regard to scores of others forfeited for similar reason. In the meantime, many such properties to which former owners are carrying deeds have been re-staked. The situation has caused a sensation in Ontario mining circles. A general request for re-instatement is being made.

On October 31, the Coniagas Mines closed a successful fiscal year. Net earnings exceeded half a million dollars. The annual statement is being prepared and will be issued in December. Ore developed on the Keeley Silver Mines since work was resumed early this year is estimated to contain 400,000 oz. of silver. The newly installed 20-stamp mill is now in operation. The Chambers-Ferland has made arrangements to explore part of its property through a shaft on the Right of Way Mines Co. Cross-cutting is under way at a depth of 385 ft., and it is planned to explore thoroughly that part of the property lying between the Nipissing and the La Rose. Fire recently destroyed the first shaft-house to be constructed in Cobalt, on the La Rose property. The miners were removed without injury or loss through another shaft, but operations were delayed some days on account of the damage done to machinery and equipment.

PORCUPINE.—The Dome Mines, for the five months ended August 31, reports a surplus after charges and taxes of \$198,467, equivalent to 49c. per share on its capital stock of \$4,000,000. The report that the Dome had purchased 26 additional machines for underground work to be ready for an influx of mine-workers from England is officially confirmed.

At the annual meeting of the shareholders of the North Davidson the financial statement submitted showed that \$73,256 had been expended in development. R. T. Jeffrey, president, stated that the results from diamond-drilling were beyond expectations, assay from three drill-holes giving an average gold content of about \$25 per ton. A 4-ft vein, stated to be very rich, has been cut at a depth of 52 ft. in the shaft.

KIRKLAND LAKE.—The Lake Shore during September produced \$40,150 from the treatment of 1480 tons of ore, the average recovery being \$27.12 per ton. Sinking was done to the extent of 54 ft. The Ontario-Kirkland has decided to delay the construction of its mill until spring in the expectation of lower prices for material. At the Kirkland Lake the 900-ft. level, the deepest in the camp, is being opened. The mill is treating 125 tons of ore per day. A drift started on the 400-ft. level has been halted owing to labor shortage.

MEXICO

GOVERNMENT TO BUILD ROADS.

SONORA.—It is reported that the Government will aid mining interests of Sonora. The first help to be extended will be received by the Puertocito mine, situated south of Naco and Cananea. This mine is being operated under serious difficulties for the reason that the road leading from the camp to highways running into Cananea, Naco, and Agua Prieta are practically impassable. In addition the road, which is really a trail, is dangerous to travel. Engineers sent into the district reported that it was possible to construct a good road, and plans for such a highway have been forwarded to Mexico City. It is understood that a sum of \$20,000 has been made immediately available in order to make the roads passable.

CHIHUAHUA.—Announcement is made that the Bernice mining company expects to begin shipments of high-grade silver-lead ore from its properties in Mexico to the smelter at El Paso. The properties are situated near Comidor, within a mile of the Rio Grande, in the State of Chihuahua, and about 30 miles south-west of Valentine, Texas.

Robert Rae, formerly chief auditor for the Phelps Dodge Corporation at Douglas, Arizona, has recently returned from a visit of several weeks to the State of Chihuahua. He reports industry to be reviving and peaceful conditions everywhere. The American Smelting & Refining Co. is active in getting its properties back into operation, and the same can be said of the Alvarado Mining Co. of Parral. The opinion prevails that within the present year many important mining operations in the State of Chihuahua will return to normal.

THE MINING SUMMARY

ALASKA

Juneau.—A property which gives promise of developing an important producer of gold now is being opened up on Chichagoff island. Work is being continued throughout the winter by the Falcon Mining Co. A tunnel has been driven for 220 ft. and it is said that the showings are so encouraging that the owners plan to commence shipping in a short time.

CALIFORNIA

Amador County.—The Central Eureka company has increased mine development and will shortly start another unit of the mill. Excellent ore continues to be drawn from the 3900-ft., with the orebody on that level developing well. —With the pumping plants in the Argonaut and Kennedy shafts operating with a full head, unwatering of the Argonaut workings is making rapid progress. Withdrawal of restrictions regulating use of electric power has materially aided rapid clearance of the shaft. The workings have been found in good condition as the water is lowered and comparatively little repair work will be necessary before actual mining is resumed.

Plumas County.—The high cost of power, coupled with high wages and freight-rates and the declining price of copper, are reasons assigned by the Walker Copper Co. for laying-off the majority of its miners and suspending copper production. Only a sufficient number of the crew is to be retained to maintain development and construction work. The mine has been employing 170 men. —The Gruss Copper Co. reports the intersection of the main east-west vein on the 200-ft. level. The discovery was made 350 ft. north of the shaft and a large body of rich ore is said to be exposed. A raise is advancing on the vein to connect with the old Kalfus workings. Plans are under consideration for erection of a mill with a capacity of 200 tons of ore per day. —The Engels Copper Co. is preparing to increase development work, despite the unfavorable copper market, in order that the company may be in a position to take full advantage of more favorable conditions. At present 450 men are employed with development of new territory receiving prime attention. The flotation-plant is running steadily.

Redding.—The work of tearing down the Balaklala Copper Co.'s smelter at Coram has been completed and most of the structural steel has been delivered at Bully Hill, or Winthrop, where it will be used in erecting works for the Shasta Zinc & Copper Co. The foundations for the Bully Hill buildings are complete.

COLORADO

Breckenridge.—Contrary to a recent report the Tonopah Placers Co. has not ceased operations in this district.

Silver Plume.—Donald H. Fairchild has completed an examination of the Dives, Pelican, and Seven-Thirty mines and a series of mill-tests on ore collected from the mine dumps. The Wasatch-Colorado mill was used for the test-run while the jig and table tailings were taken to Denver for further tests by flotation. A net recovery of 94% of the silver was obtained. It is probable that the present mill will be re-modeled and operation of the mines resumed.

IDAHO

Coeur d'Alene.—Frank Murphy, of Spokane, has received \$100,000 for two claims which the Coeur d'Alene syndicate has purchased in acquiring the Flynn claims. In addition he retains 50,000 shares of stock in the Senator Mining Co., the property which was included in the purchase. This is one of the first cash payments in this transaction, which is one of the most important in many years in the district. —Good ore has been found in the Nevada-Stewart property adjoining the Highland-Surprise on Pine creek. Seven feet of vein is filled with stringers of lead-zinc ore and in one place there is one foot of almost clean ore.

H. W. Steadman, manager of the Paragon mine, states that he is working two small forces, one on the Black Horse property and the other on the Chicago. "Good ore is being uncovered, especially in the Chicago," said Mr. Steadman. "The zinc in the ore is being replaced by galena. The ore is improving, which indicates we may have large orebodies with depth. The company intends to continue its shaft 400 ft. which will give a depth of almost 900 ft. on the vein."

—Ore from Alaska is coming to the smelter at Kellogg, but until freight-rates are adjusted no great tonnage is expected from outside of the Coeur d'Alene district, according to F. W. Bradley, president of the Bunker Hill & Sullivan company.

"We must find one," was his reply when asked if the Bunker Hill & Sullivan company will find a method of treatment of the zinc-lead ores of the Coeur d'Alene. "It is most important to the district that such a solution be found and we are continually carrying on experiments. We will find it if possible." —Work at the American Commander mine is progressing. The company is fixing up winter quarters for its men and will resume development work. It is reported that a vein 10 ft. wide, containing considerable galena, was found in cross-cutting from the bottom of the shaft.

Wallace.—C. W. Newton, manager for the Consolidated Interstate-Callahan Co. confirms the report that his property will suspend operations early in November. This will result in the discharge of about 350 men employed in the mine and mill. During the suspension of shipments, underground development will be carried on, but Mr. Newton was unable to say how many men will be retained for this work. It is stated that the principal reason for the suspension of operations is due to a strike of the smelter employees of the Grasselli Chemical Co., which strike was begun in September. The October production of ore was the largest in any recent month. No statement has been made as to the probable length of the period of inactivity.

MISSOURI

Joplin.—The shut-down that had been in effect throughout the district for two weeks ended the first of November and a number of mines resumed operations the following morning. A number of other mines that observed the shut-down started several days later. The managers were of the opinion that it would be better to wait two days longer and start work with a complete force than to try to operate with an insufficient number of men. The continued curtailment of ore production will be carried out as effectively as possible. The demands on the district are for about 7000 tons

per week and production will be held to this amount if possible. Operators are agreed that further curtailment is necessary and are showing a spirit of co-operation that is encouraging, as it is felt that in this way only can the best interests of the industry be served.—The Richardson mines, at Quapaw, have started and will run on two shifts. The company has been reorganized since the mill shut-down several months ago, and now is under the direction of a strong company composed of Texas and Oklahoma men. The mill has a capacity of 500 tons in 20 hours, and the endeavor will be to run at full capacity. An assay shows 5.41% lead and 13.06% 'jack', secured from an 18-ft. face of ore. An electric pump has been installed and will have capacity sufficient to handle the heavy flow of water. The mill will be run with a modern gas engine, while the hoist is operated by steam. W. E. Sheatham is the superintendent in charge. —The new shaft being sunk at the Vantage mine in Picher is down about 125 ft. and will be continued as rapidly as possible until the orebody is reached. The shaft is on Netta street, near the edge of the lease adjoining the St. Joe property. As soon as the shaft is ready for operation a dummy line will be built to the mill at Third and Treece streets. The mill has undergone extensive repair in the last few weeks.—The Dorothy Bill mine is working on ore obtained from a new shaft recently sunk north-east of the mill. The ore is rich in both lead and zinc and is expected to prove one of the richest lead producers in the district. The ore is being transported to the tramway in cars pulled by mules.

NEVADA

Eureka.—During the past two weeks 33 cars of ore and speiss have been shipped out over the Eureka-Nevada railway, consigned to the Utah smelters, for treatment.—At Ruby Hill, the water in the Locan shaft has been giving less trouble, only 600 gallons per minute being made. It has been held down to the 1200-ft. level, where a station is being cut. A second station-pump will be installed. Ore is being blocked out on the Locan 900-ft. level.—At the Eureka-Croesus mine the No. 8 winze is down 50 ft., the last 27 ft. being in good shipping ore. The 'shale' winze is yielding ore of good quality, and some of the old workings of the Dunderberg mine are producing a little good shipping ore.

The Holly mine is a steady producer of good shipping ore. The drift from the shaft, at a depth of 430 ft., broke into the Williamsburgh workings about 10 days ago, and a track has been laid from the point of connection to the Bullwhacker ground. A connection is thus established with the Holly shaft at the 500-ft. level, which admits of the removal of Bullwhacker ore through that thoroughfare.—Four carloads of materials for the construction of the Holly milling plant arrived a few days ago.—Eureka appears dull at present to the casual observer, but there is more prospecting under way in the Prospect Mountain and other outlying small mines than was ever before known in the district. All of the old-time miners in the district are impressed with the belief that ore will be found either in the Locan shaft, at an additional depth of 500 ft., or by drifting therefrom. There is reason, from a geological standpoint, to believe that ore will be found in the lower Ruby Hill wedge of brecciated limestone.

YUKON TERRITORY

Dawson.—With reference to the Mayo Silver camp, some 200 miles from here, Alfred Thompson, M. P. for the district, states that he will ask the Dominion government to build a road to the district, provide either wireless or telegraphic communication, and build an assay-office. He anticipates that the development of the silver deposits will bring the Yukon into prominence again as a mining centre and will assure Dawson a permanence which the placer industry has failed to do.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. M. Callow is in New York.

Maurice W. Summerhayes is in San Francisco.

William Burns is going to the copper mines of Michigan.

Walter Fitch Jr., mining contractor of Eureka, Utah, is in Alaska.

Errol MacBoyle, of San Francisco, is examining mines in Mexico.

Donald M. Liddell has moved his office to 2 Rector street, New York.

E. B. Lighthill has closed his office in London and is now established in Paris.

F. W. Collins expects to return to Oakland from Peru in time for Thanksgiving.

Spencer C. Browne has opened an office as consulting engineer at 2 Rector street, New York.

A. H. Jones is in New York, in consultation regarding the erection of a large mill in New Mexico.

Donald H. Fairchild has been examining the old Pelican and Dives mines at Silver Plume, Colorado.

W. J. Loring and **John F. Davis** are attending the meeting of the American Mining Congress at Denver next week.

Norman C. Stines was in San Francisco this week on his return from Nome. He is now on his way to New York.

George Kingdon, general manager for the United Verde Extension Mining Co., has recently returned from a trip to Europe.

H. B. Tooker, traffic manager of the Jackling interests, has returned to San Francisco after a trip to New York and Washington.

H. V. Burgard, secretary of the Mineral Metal & By-Products Co., of Denver, has returned to Denver from the Pacific Coast.

Edward H. Benjamin has moved his office from the Nevada Bank building to the Balboa building, at 593 Market street, San Francisco.

Frank T. Eddingfield has been appointed Valuation Engineer in the Metals Division of the Income Tax Unit, Internal Revenue Bureau.

O. C. Ralston, of the U. S. Bureau of Mines, has returned from Alaska, where he inspected the practicability of the establishment of a smelter.

R. D. Maxfield and **E. M. Tripp**, of Salt Lake City, are making an investigation of a placer-mining property in White Pine county, Nevada.

J. Fred Johnson, superintendent of the Chief Con. Mining Co. at Eureka, Utah, has been making an examination of a gold property in California.

L. D. Jenssen, superintendent of the Lokken iron mines in Norway, is visiting mining districts in this country, and spent several days in Utah.

Alan M. Bateman, mining geologist, has been engaged in professional work in Alaska and British Columbia, and has returned to New Haven, Connecticut.

Charles Butters and **H. N. Lawrie** addressed the New York section of the Institute on November 3, the first on the subject of silver, the second on the gold problem.

J. O. Lewis, chief petroleum technologist of the Bureau of Mines, has tendered his resignation to Dr. F. G. Cottrell, Director, to become effective November 15. Mr. Lewis will be succeeded by **A. W. Ambrose**, who has for some time occupied the position of superintendent of the Bureau of Mines petroleum experiment station at Bartlesville, Oklahoma.

THE METAL MARKET

METAL PRICES

San Francisco, November 9

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	16.50-17.00
Lead, pig, cents per pound.....	7.50-8.50
Platinum, pure, per ounce.....	\$95
Platinum, 10% iridium, per ounce.....	\$135
Quicksilver, per flask of 75 lb.....	\$55
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

November 8.—Copper is quiet and firmer. Lead is dull but easy. Zinc is inactive but steady.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

RAILROAD FINANCING

Now that the Transportation Act, giving the Commerce Commission control over issuance of securities, and also, to a certain degree, over application of proceeds, is in force, it is becoming apparent that railroad financing methods will undergo some modification.

Banking firms, particularly the primary houses which are first purchasers of most larger security issues, have realized some of the implications of the new order, not with unmixed satisfaction. They are aware that plants for security issues and for reorganization must be submitted to the Commission's division of finance, which is required to hold a public hearing on each application. This means some delay, and that involves the delicate and troublesome task of timing a public security offering to the capricious appetite of the investment market.

With a haunting memory of weary months through which rate cases used to drag, some Wall Street bankers have been apprehensive that time consumed in obtaining Federal authority to sell securities would mean the railroads might fall into the chronic condition of 'missing their market'. Such apprehensions, if one may judge from events to date, are groundless, for at least two reasons. One is that the division of finance, under Director Colston, a man of long experience in railroad law and finance, has been quick to see the need of expedition in affording a railroad needed capital. The other is that such applications, on forms prepared by the division of finance, are submitted in such detail that little time is required in the hearing to bring out all pertinent facts. As a rule, no opposition develops.

The mere fact that Federal control of securities has actually supplanted that of the dozen or more States which formerly exercised such powers, is admittedly a great offset to any possible disadvantage. That was the purpose of the law, and to all intents it has been achieved. In one case a State in which the applicant carrier operates made a formal effort to save its jurisdiction of securities, but apparently nothing has come of it, at least not yet.

In official circles it is doubted whether the banking community fully realizes the willingness of the Commerce Commission to facilitate necessary and legitimate work of financing railroads. In approving a certain issue of bonds, the Commission commented that the bonds had been sold by the railroad, subject to approval of the Commission. In some Wall Street quarters the comment was interpreted as disapproval of such a practice. It should not be supposed that a sale of bonds in advance of the Commission's action could ever be regarded as a successful means of bringing pressure to bear on the Commission to approve an issue it would not have approved otherwise, and in advance of the sale. No such case has arisen, and the Commission has no idea that any will. But this is a new function of the Commission, and precedents to govern it in future are in the making.

Probably the most important effect of Federal securities regulation will be that railroads will make financial plans further in advance than heretofore considered necessary, and may even adopt the practice of obtaining Commission approval of financial plans long before intended execution. The secrecy which bankers and railroad executives have habitually regarded as an essential part of their negotiations, up to moment of a public offering, may become a less binding rule.

MONEY AND EXCHANGE

Foreign quotations on November 9 are as follows:

Sterling, dollars: Cable	3.37 1/2
Demand	3.38
Francs, cents: Cable	5.84
Demand	5.85
Lire, cents: Demand	3.45
Marks, cents	3.21

Eastern Metal Market

New York, November 3.

Buying initiative is largely absent from all the markets. While the price movement is still downward, it is less strongly so.

Copper has reached the 15c. level with little response by consumers, though they recognize its cheapness.

The tin market is firmer but buying by consumers is light; it is also speculative.

There is little demand for lead and prices are a little lower.

Quotations for prime Western zinc have receded slightly with light offerings and little demand.

Antimony is lower.

IRON AND STEEL

Pig-iron producers have made a quick response to the falling off in consumption, says 'The Iron Age'. Thirty-two fewer furnaces were in blast November 1 than one month previous—a falling off that has few parallels. October production of pig-iron held up well, the total being 3,278,104 gross tons, or 105,745 tons per day, as against 3,129,323 tons in the 30 days of September, or 104,310 tons per day. Thus October was the record month of the year, apart from March, and only January showed a larger total in 1919. Thirty-five furnaces blew-out last month and only three blew-in, and 287 furnaces were active November 1, against 319 one month previous.

In pig-iron as in steel the Steel Corporation's production has been nearer capacity than that of other makers, in view of the considerably larger tonages on its books in all lines.

With furnaces blowing-out, coke is more plentiful and another \$2 has come off the price, making a decline of about 50% in three weeks. From \$9 to \$10 has been paid for furnace-coke, with a downward trend still indicated.

COPPER

Copper, both electrolytic and Lake, can be bought from most of the large producers as well as in the outside market as low as 15c. for delivery in the next two months and at 15.25c. for delivery in the first two months of 1921. The entire situation is not spoken of by large producers as encouraging or satisfactory and whether the bottom has been reached they have no opinion. The market has been slashed and they know it and are trying to make the best of it. Perhaps small lots could be obtained down to 14.75c., but not yet from large producers. Buying is a little better than a week or two ago, but it is inconsequential. Stocks are admittedly heavy and production is being curtailed further. There is one ray of hope in that it is recognized that some day Europe must buy, for she needs copper in vast quantities and can get it nowhere else. There was a sale of 400 tons on the New York Metal Exchange Monday at 14.82½, 14.77, and 14.70c., all under the rule, in lots of 200 tons, 100 tons, and 100 tons respectively.

TIN

An explanation of the present unsatisfactory market and low prices is offered in the opinion that there are few buyers, too many sellers, and bad financial conditions. Relatively tin is very low in this market. Consumers here are probably using invisible supplies. The orders that have been afloat lately have been taken mostly by one large company, it is said. As a result the market is stale and dull and, despite the advance in London since early in the coal strike and especially since its apparent settlement, buyers still hold off. In the past week there have been still more sales under the rule on the New York Metal Exchange amounting to about 150 tons of both spot and future-shipment metal at prices ranging from 39.30 to 41.25c. On

Monday last spot Straits tin was quoted at 39.50c., New York, yesterday having been a holiday. The price has hovered around 40c. for a week or so. In London the metal has advanced and on Monday spot standard stood at £266 per ton, future standard at £267, and spot Straits at £270, the latter £10 above the price on October 26, a week ago. Deliveries into consumption in October were 3415 tons, of which about only 315 tons is credited to Pacific ports. Stocks and landing on October 31 were 3191 tons.

LEAD

This market is flat and dull—featureless in the extreme. The only item of interest is the fact that the domestic market is now below the cost of importation which will remove that competitive factor perhaps for some time. The cost of importation is not less than 7.50c., duty paid, seaboard, while spot and shipment-lead as well as metal in transit is offered and sold at 6.90c., New York, with liberal offerings at 6.65c., St. Louis. Demand, however, is not equal to the supply, and consumption is on the decline. The leading interest has not yet changed its quotation of 7c., St. Louis, or 7.25c., New York.

ZINC

The market has a better tone than in some weeks and may be pronounced as considerably steadier. Prices for prime Western have, however, receded again to 6.90c., St. Louis, or 7.40c., New York, which we quote as the domestic market for early delivery. There is still some imported zinc re-shipped from foreign ports, available at around 7.25 to 7.35c., seaboard or New York, but the quantity is not large and this material is less and less a factor.

ANTIMONY

There is no animation to the market and quotations for wholesale lots are nominally lower at 6.37½c., duty paid, New York, for spot and early delivery. Jobbing lots are quoted at 6.62½ to 6.87½c., New York.

ALUMINUM

No changes have developed. The leading producer's quotation for virgin metal, 98 to 99% pure, is still 32.90c. per pound, producer's plant, while in the outside market the same grade is quoted at 28 to 29c., New York.

ORES

Tungsten: There is no business and prices are nominal at \$4.50 per unit for Chinese ore and \$5 to \$5.50 per unit for Bolivian ore. There is some inquiry from Europe, but direct shipments to Europe are reported cheaper from countries of origin than American shipments.

Ferro-tungsten is quoted at 90c. per pound of contained tungsten in guaranteed lump form and at 70c., not guaranteed, while the powdered variety is quoted at 78 to 85c. per pound.

Molybdenum: The market is flat and nominal at 75c. per pound of MoS₃ in regular concentrate.

Manganese: The quotation for high-grade ore is 45 to 50c. per unit with demand light. Importations continue very heavy, those for September having been 88,422 gross tons against 99,601 tons in August.

Manganese-Iron Alloys: Re-sale material dominates the market for both ferro-manganese and spiegeleisen. The former is obtainable in small quantities at \$155, basis seaboard, and some sales have been made at this level. The regular quotation of producers is on a basis of \$170, seaboard, for both foreign and domestic alloy. The nominal quotation for spiegeleisen is \$75 to \$80, furnace, with re-sale material available as low as \$60. Sales have been made as low as \$58.75. Importations of ferro-manganese in September were 6524 gross tons with the exports reported as 297 tons.

No Bigger Than A PENCIL POINT —Yet Irresistible

THE TINY FLAME of the Oxweld torch has given man complete control over Nature's most stubborn elements.

Man's inventive genius improved metals to meet his growing demands—toughened, hardened and strengthened them. And then, in order that he might fashion these super-elements to meet his needs, he called into being the oxwelding process.

The hardest of steels offers no difficulty to Oxweld—it is built up or joined as occasion demands or is cut by the Oxweld cutting flame as a knife slices butter.

Laborious and costly production processes are being replaced, everywhere, by Oxweld with speedier, less expensive and more satisfactory methods.

It prevents profit-eating delays by repairing breaks on the spot in short order and it forestalls break-downs by building up worn parts.

Oxweld Service Engineers are ready to tackle your problems. Write, wire or telephone to any of the addresses below for immediate attention.

OXWELD ACETYLENE COMPANY

NEWARK, N. J. CHICAGO SAN FRANCISCO

T. A. RICKARD, Editor

ACCORDING to official statistics received from Mexico City, the production of silver in Mexico during the year 1919 was 65,900,000 ounces, as against 62,500,000 ounces in 1918 and 42,000,000 in 1917. In 1915 the production was only 22,000,000 ounces.

AT the end of the first week in November the United States Mint had purchased 21,644,231 ounces of silver under the terms of the Pittman Act. Coinage during October included a million half-dollar pieces, 4½ million quarters, and 6½ million dimes, in addition to 70 million nickel and copper coins. Gold coinage was suspended throughout the month.

IN this issue we publish a short account of the food-draft scheme as put into successful operation by the American Relief Administration. The writer of the article, Mr. Edgar Rickard, needs no introduction to our readers. We learn from him that California ranks fifth in the purchase of food-drafts, having purchased 9212 drafts, equivalent to \$151,950 worth of food delivered in Europe. Altogether \$5,239,000 worth of food has been distributed by this method. Any profit is turned over to the European Children's Fund.

ON November 16 the Calumet & Hecla Mining Company, together with its subsidiary enterprises, put into effect a cut of 15% in the wages and salaries of all its employees. At the same time a number of mines in the Michigan copper region, including Osceola Consolidated, White Pine, and La Salle, discontinued production entirely, and the forces at other properties were reduced, thereby throwing 1500 men out of work. There has been no profit in the copper-mining industry of Michigan for two years; some metal was being marketed, however, and most of the mines were kept in operation. Stocks of unsold copper, the limited market, and the current low price have combined to compel this recent drastic move. Similar action is reported from Bisbee and Jerome, except that the wages of the employees retained on the payroll have not been cut. Whenever there is any considerable reduction in the number employed the output per man automatically increases, so that direct mining costs are lowered. Apparently the operators in Arizona are content with this improvement without resorting to reductions in the wage-scale, at least until such time as a definite decline in the cost of living is demonstrable. It seems certain that prices will go down

and that reduced wages will be the logical consequence. The action taken in Michigan is predictive of the general readjustment.

HOW much should a gold mine pay to be an attractive speculation? We find the suggestion of an answer to this query in a tabulated statement of the capital, dividends, and yield of the principal mines of the Witwatersrand. Our contemporary, 'The Mining World', of London, gives the data for 27 mining companies, of which we set aside three, because their mines are approaching exhaustion and therefore are expected to pay dividends that represent amortization rather than current interest. The remaining 24 show a yield of 14% per annum on the current market valuation of their properties. This indicates that the British public has learned from bitter experience to realize the essentially speculative character of all gold mining and now demands a rate of return commensurate with the inescapable risk. The greatest gold mine in the world, the New Modderfontein, pays 12% on its market price. We remember the days when the promoters and financiers of the Rand used to talk about 6% and 7% as sufficient interest and recommended their shares as fit investments for the trustees of widows and orphans. Most of the promoters liquidated their own holdings at top prices, leaving the public with an impoverished pocket and an enriched experience. The realization of the speculative character of gold mining on the Rand, or elsewhere, will not hurt the mining industry; it will serve chiefly to distribute the profits more fairly between the insiders and the public.

BUTTE is one place where the local issues decided at the election easily eclipsed in importance and interest the question of President Wilson and the League or any other national issue. It was the old fight of the radical labor element against the Anaconda Copper company; fortunately the business people of Butte and the more conservative miners and craftsmen decided in favor of the mining company. Incidentally the Republican ticket won in a city that always has been the stronghold of the Democratic party in a habitually Democratic State. At the primaries held some months ago Mr. William F. Dunn, publisher of a radical newspaper, the 'Butte Daily Bulletin', and eight or ten others whose sympathies were known to be with the more radical mine-workers, won nominations on the Democratic ticket for several important offices, including those of Sheriff and

District Attorney. Thereupon the charge was made that the Democratic party had been "stolen" and the Anaconda company, largely through the medium of the 'Anaconda Standard', a newspaper that has always been Democratic, started a bitter fight to defeat the 'wobblies' on the Democratic ticket. The Anaconda company professes to take no part in politics, but mining is the only productive industry in or near Butte and the Anaconda enterprise is so much bigger than all the other mining operations combined that it is conceded leadership. Without imputing any sinister motives, it may reasonably be said that the company cannot help being vitally interested in politics, and, while the new city and county officials will not, as the 'Bulletin' charges, take their orders directly from the "sixth floor" (alluding to the Hennessy building, where are the offices of the Anaconda company), we venture that the wishes of the company officials regarding the conduct of municipal and county affairs will be given respectful consideration. Any other view would necessarily attribute to the successful candidate a type of independence that is seldom displayed by astute politicians in Butte or elsewhere. During the campaign the threat was made unofficially that operation of the mines would be suspended indefinitely in the event that the objectionable Democratic candidates were elected. On the day before election the 'Bulletin' said on its front page, "If the Republican ticket is elected the wages of the miners and the craftsmen will be cut and those who object will be baptized with shrapnel and machine-guns"; while the 'Standard', on Tuesday, declared in a seven-column head, "The Destiny of Butte will be decided at the Polls today", and on the day following said, "It was a sweeping victory, not for the Republican party, but for law and order, for honesty, decency, and good citizenship". The officials of the Anaconda Copper company doubtless have made blunders at times in their dealings with the miners, and with the unions, but the crowd of which Mr. Dunn is a leader has repeatedly avowed allegiance to the principles of anarchy, to sabotage, and to violence. Nothing good could possibly come from their election to office, and Butte is to be congratulated on the result of the balloting. To what extent the local issue helped the Republican national ticket, and how much the sentiment for Senator Harding favorably affected the vote for the candidates on the Republican county ticket, can only be guessed; at any rate, the Hardinge-Coolidge electors received a substantial majority in Silver Bow county, of which Butte is the county-seat.

WE went to press last week too soon to be able to record the meeting of the San Francisco section of the Institute at which Mr. Hoover was present in his official capacity as president of the Institute. A large attendance graced this special occasion and Mr. Hoover made it memorable by a speech crowded with interesting information. He referred to the increase of membership this year, an increase that, we venture to suggest, is due largely to the fact that our president is a man who himself illustrates supremely the chief function of the en-

gineer as one who converts the resources of nature to the use and benefit of man. In his own career during recent years Mr. Hoover has provoked a comparison between the destructive performances of the diplomat and the constructive activities of the engineer. He told his audience something about the proposed Federation of Engineers, the organization of which is to be perfected at a meeting in Washington on the 17th instant. He touched upon the intermittency of labor in the coal regions, giving 180 shifts per annum as the coal-workers average portion, and emphasized the economic necessity for systematizing the extraction, storage, and distribution of coal so as to prevent the waste of time, energy, and money. Speaking of the defective distribution of power in the industrial region of the Atlantic seaboard, he mentioned a project for building an electric trunk-line from Washington to Maine to be used as a means for conducting power and distributing it over branch-lines to industrial centres. In response to a question, he described the work being done by the American Relief Administration, and in response to another question, he dwelt upon the utter failure of communism in Russia, suggesting a warning to our radicals and dreamers. He urged all present to bring pressure upon their representatives in Congress to support the bill for a Federal Department of Public Works; in short, he gave us a crowded hour of live information and stimulating thought.

A RECENT discovery in Canada affords a nice illustration of the incidence of economic considerations on the technical distinction between a 'mineral deposit' and a deposit of 'ore'. The former, of course, is the more comprehensive term. It is reported that on August 25 oil was found at a depth of 783 feet in a drill-hole near Fort Norman, which is situated on the Mackenzie river and near the Arctic circle. The six-inch casing was capped after flowing for half an hour at a rate estimated at 1500 barrels per day. Whether this estimate be accurate or not is immaterial; there seems to be evidence of the existence of a good supply of oil. However, even if a hundred wells of this size were 'brought in' near Fort Norman, they would have no economic value as an immediate source of petroleum products for southern Canada and the United States. From Fort Norman to the nearest railroad is 1200 miles and to the nearest navigable river the distance is approximately 900 miles. Numerous streams capable of floating boats of shallow draught appear on the map to afford a route, but sundry rapids necessitate frequent portage, thereby precluding the shipment of a bulky cargo. Moreover, on account of the Arctic cold the rivers are open to navigation for only a few months during the year. The construction of a pipe-line, according to the engineers of the Imperial Oil Company, would involve an expenditure of some \$50,000,000, so that there is little likelihood of such a project being undertaken until various other sources of supply have been exhausted. Obviously, if enough productive districts were discovered in the region and if the demand, and consequently the price, were increased sufficiently, the difficulties of exploiting the oil would be

overcome. We venture to say that the shale of Colorado and Utah will have been made to yield the tremendous quantities of oil that they contain before we turn to the Arctic region as a source of crude petroleum.

The Bingham Decision

In this issue we publish the larger part of the opinion handed down by Judge Tillman D. Johnson, of the U. S. District Court for Utah, on October 20, in the first of a series of suits between the Utah Apex Mining Co. and the Utah Consolidated Mining Co. arising from disputes over the ownership of ore in sundry beds of limestone at Bingham, Utah. The trial was completed last January, at which time Judge Johnson took the cases under advisement. In the two principal controversies no vital question of apex or extra-lateral rights arose. The expert witnesses on both sides agreed so closely as to the position and physical characteristics of the beds and lodes that the Utah Apex company agreed to accept the maps and other exhibits of its opponents as correctly representing the conditions existing in the two mines; the two geologic sections given elsewhere in this issue are adapted from the exhibits of the Utah Consolidated company. They present the salient points clearly. The section on page 727 shows the issue in the first case, wherein the Utah Consolidated was the defendant. The Utah Apex company sought to recover \$1,750,000 for ore that, it alleged, had been wrongfully mined by the Utah Consolidated from the Leadville orebodies. The defendant contended that the Highland Boy limestone stratum was a continuous broad lode, and so designated it on its exhibit. In our drawing we have substituted the words 'limestone bed' for 'lode', to conform with the decision of the Court. The geologists who testified for the Utah Consolidated defined a lode as "mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized, then it becomes a lode. Just as soon as either of the other rocks can produce and to produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it in expectation of finding ore, then it becomes a lode." Around this definition of the statutory meaning of 'lode' the argument of the defendant was built. The cases of *Richmond Co. v. Eureka Co.* and *U. S. Mining Co. v. Lawson* were cited by the defendant, who urged that the conditions were so nearly parallel that those decisions, wherein the courts had held that particular limestone beds fulfilled the requirements of the definition of 'lode', should be accepted as a valid precedent. The Utah Apex attorneys contended that the Highland Boy ore deposit is a broad lode limited by the porphyry dike, shown immediately to the right of the principal stopes, and offered evidence to prove that for a distance of a quarter of a mile between the Highland Boy and Leadville orebodies the limestone is unaltered, and that the adjacent quartzite contains more lead than does the limestone; they argued that the two orebodies were entirely independent

of each other. In his findings Judge Johnson points out that the limestone strata in the cases cited were so broken, crushed, and fissured, and so impregnated with metalliferous minerals as to be clearly distinguished as lodes; but that this does not appear to be true with respect to the limestone in the present controversy. He declares that he cannot escape the conviction that, in the course of twenty years of profitable mining, the defendant would have explored the long stretch of limestone between the two orebodies, had there been "reasonable expectation of finding ore." The decision sustains the contention of the Utah Apex company that the limestone is not a lode, and that the orebodies are identified with sundry steeply pitching fissures, variously called faults, fault-fissures, fissure-zones, and fissure-veins by the geologists who testified at the trial. A slightly different question is involved in the second suit as illustrated in the sectional drawing on page 729. Here the positions are reversed in that the Utah Consolidated company alleges wrongful extraction by the Utah Apex of ore in the Yampa limestone bed, the orebodies in controversy being indicated by the stopes above and below the Apex 1300-foot level. The plaintiff had mined a foot-wall vein which follows the contact between the limestone and the underlying quartzite; the contention was again made that the limestone forms a thick lode; it was argued that any orebodies within its limits are part of the lode. The Utah Apex conceded the ownership of the Yampa foot-wall vein, but denied any geologic connection between this vein and detached orebodies in the overlying limestone. We have not printed the decision of the Court in this case, since the conclusions are reached by much the same line of reasoning. The Utah Consolidated company, since the announcement of the decision, has voluntarily discontinued mining the Leadville orebodies, and its engineers are now engaged in calculating the value of the ore wrongfully removed. This estimate will be subject to exception by the Utah Apex company, in which event the Court will be called upon to determine the amount of damage.

The Divining Rod

By way of introduction, we may say that a few days ago a man called at this office to ascertain where he could buy a divining rod, which he wanted for use in finding some buried gold near Vallejo, at the northern end of the Bay of San Francisco. He was shown the proof of the article by William Pryce, appearing in this issue, and he asked particularly for the drawing given by the old Cornishman because he intended to make a divining rod for himself.

On another page we publish an excerpt from that remarkable old book, 'Mineralogia Cornubiensis', by William Pryce, of Redruth. This book, which is the 'Agricola' of Cornwall, was published in 1778 and is full of genuine information on mining affairs. Among other subjects discussed by Dr. Pryce is the divining rod, to which he gives the larger part of a chapter headed, 'Of the various Methods of discovering Mines'. His remarks on

District Attorney. Thereupon the charge was made that the Democratic party had been "stolen" and the Anaconda company, largely through the medium of the 'Anaconda Standard', a newspaper that has always been Democratic, started a bitter fight to defeat the 'wobblies' on the Democratic ticket. The Anaconda company professes to take no part in politics, but mining is the only productive industry in or near Butte and the Anaconda enterprise is so much bigger than all the other mining operations combined that it is conceded leadership. Without imputing any sinister motives, it may reasonably be said that the company cannot help being vitally interested in politics, and, while the new city and county officials will not, as the 'Bulletin' charges, take their orders directly from the "sixth floor" (alluding to the Hennessy building, where are the offices of the Anaconda company), we venture that the wishes of the company officials regarding the conduct of municipal and county affairs will be given respectful consideration. Any other view would necessarily attribute to the successful candidate a type of independence that is seldom displayed by astute politicians in Butte or elsewhere. During the campaign the threat was made unofficially that operation of the mines would be suspended indefinitely in the event that the objectionable Democratic candidates were elected. On the day before election the 'Bulletin' said on its front page, "If the Republican ticket is elected the wages of the miners and the craftsmen will be cut and those who object will be baptized with shrapnel and machine-guns"; while the 'Standard', on Tuesday, declared in a seven-column head, "The Destiny of Butte will be decided at the Polls today", and on the day following said, "It was a sweeping victory, not for the Republican party, but for law and order, for honesty, decency, and good citizenship". The officials of the Anaconda Copper company doubtless have made blunders at times in their dealings with the miners, and with the unions, but the crowd of which Mr. Dunn is a leader has repeatedly avowed allegiance to the principles of anarchy, to sabotage, and to violence. Nothing good could possibly come from their election to office, and Butte is to be congratulated on the result of the balloting. To what extent the local issue helped the Republican national ticket, and how much the sentiment for Senator Harding favorably affected the vote for the candidates on the Republican county ticket, can only be guessed; at any rate, the Hardinge-Coolidge electors received a substantial majority in Silver Bow county, of which Butte is the county-seat.

WE went to press last week too soon to be able to record the meeting of the San Francisco section of the Institute at which Mr. Hoover was present in his official capacity as president of the Institute. A large attendance graced this special occasion and Mr. Hoover made it memorable by a speech crowded with interesting information. He referred to the increase of membership this year, an increase that, we venture to suggest, is due largely to the fact that our president is a man who himself illustrates supremely the chief function of the en-

gineer as one who converts the resources of nature to the use and benefit of man. In his own career during recent years Mr. Hoover has provoked a comparison between the destructive performances of the diplomat and the constructive activities of the engineer. He told his audience something about the proposed Federation of Engineers, the organization of which is to be perfected at a meeting in Washington on the 17th instant. He touched upon the intermittency of labor in the coal regions, giving 180 shifts per annum as the coal-workers average portion, and emphasized the economic necessity for systematizing the extraction, storage, and distribution of coal so as to prevent the waste of time, energy, and money. Speaking of the defective distribution of power in the industrial region of the Atlantic seaboard, he mentioned a project for building an electric trunk-line from Washington to Maine to be used as a means for conducting power and distributing it over branch-lines to industrial centres. In response to a question, he described the work being done by the American Relief Administration, and in response to another question, he dwelt upon the utter failure of communism in Russia, suggesting a warning to our radicals and dreamers. He urged all present to bring pressure upon their representatives in Congress to support the bill for a Federal Department of Public Works; in short, he gave us a crowded hour of live information and stimulating thought.

A RECENT discovery in Canada affords a nice illustration of the incidence of economic considerations on the technical distinction between a 'mineral deposit' and a deposit of 'ore'. The former, of course, is the more comprehensive term. It is reported that on August 25 oil was found at a depth of 783 feet in a drill-hole near Fort Norman, which is situated on the Mackenzie river and near the Arctic circle. The six-inch casing was capped after flowing for half an hour at a rate estimated at 1500 barrels per day. Whether this estimate be accurate or not is immaterial; there seems to be evidence of the existence of a good supply of oil. However, even if a hundred wells of this size were 'brought in' near Fort Norman, they would have no economic value as an immediate source of petroleum products for southern Canada and the United States. From Fort Norman to the nearest railroad is 1200 miles and to the nearest navigable river the distance is approximately 900 miles. Numerous streams capable of floating boats of shallow draught appear on the map to afford a route, but sundry rapids necessitate frequent portage, thereby precluding the shipment of a bulky cargo. Moreover, on account of the Arctic cold the rivers are open to navigation for only a few months during the year. The construction of a pipe-line, according to the engineers of the Imperial Oil Company, would involve an expenditure of some \$50,000,000, so that there is little likelihood of such a project being undertaken until various other sources of supply have been exhausted. Obviously, if enough productive districts were discovered in the region and if the demand, and consequently the price, were increased sufficiently, the difficulties of exploiting the oil would be

overcome. We venture to say that the shale of Colorado and Utah will have been made to yield the tremendous quantities of oil that they contain before we turn to the Arctic region as a source of crude petroleum.

The Bingham Decision

In this issue we publish the larger part of the opinion handed down by Judge Tillman D. Johnson, of the U. S. District Court for Utah, on October 20, in the first of a series of suits between the Utah Apex Mining Co. and the Utah Consolidated Mining Co. arising from disputes over the ownership of ore in sundry beds of limestone at Bingham, Utah. The trial was completed last January, at which time Judge Johnson took the cases under advisement. In the two principal controversies no vital question of apex or extra-lateral rights arose. The expert witnesses on both sides agreed so closely as to the position and physical characteristics of the beds and lodes that the Utah Apex company agreed to accept the maps and other exhibits of its opponents as correctly representing the conditions existing in the two mines; the two geologic sections given elsewhere in this issue are adapted from the exhibits of the Utah Consolidated company. They present the salient points clearly. The section on page 727 shows the issue in the first case, wherein the Utah Consolidated was the defendant. The Utah Apex company sought to recover \$1,750,000 for ore that, it alleged, had been wrongfully mined by the Utah Consolidated from the Leadville orebodies. The defendant contended that the Highland Boy limestone stratum was a continuous broad lode, and so designated it on its exhibit. In our drawing we have substituted the words 'limestone bed' for 'lode', to conform with the decision of the Court. The geologists who testified for the Utah Consolidated defined a lode as "mineralized rock or rocks which contain such indications of valuable minerals as to justify development with the expectation of finding ore. As soon as quartzite over a considerable distance becomes mineralized, then it becomes a lode. Just as soon as either of the other rocks can produce and do produce ore, or contain indications which lead the experienced miner or prospector of judgment to develop it in expectation of finding ore, then it becomes a lode." Around this definition of the statutory meaning of 'lode' the argument of the defendant was built. The cases of *Richmond Co. v. Eureka Co.* and *U. S. Mining Co. v. Lawson* were cited by the defendant, who urged that the conditions were so nearly parallel that those decisions, wherein the courts had held that particular limestone beds fulfilled the requirements of the definition of 'lode', should be accepted as a valid precedent. The Utah Apex attorneys contended that the Highland Boy ore deposit is a broad lode limited by the porphyry dike, shown immediately to the right of the principal stopes, and offered evidence to prove that for a distance of a quarter of a mile between the Highland Boy and Leadville orebodies the limestone is unaltered, and that the adjacent quartzite contains more lead than does the limestone; they argued that the two orebodies were entirely independent

of each other. In his findings Judge Johnson points out that the limestone strata in the cases cited were so broken, crushed, and fissured, and so impregnated with metalliferous minerals as to be clearly distinguished as lodes; but that this does not appear to be true with respect to the limestone in the present controversy. He declares that he cannot escape the conviction that, in the course of twenty years of profitable mining, the defendant would have explored the long stretch of limestone between the two orebodies, had there been "reasonable expectation of finding ore." The decision sustains the contention of the Utah Apex company that the limestone is not a lode, and that the orebodies are identified with sundry steeply pitching fissures, variously called faults, fault-fissures, fissure-zones, and fissure-veins by the geologists who testified at the trial. A slightly different question is involved in the second suit as illustrated in the sectional drawing on page 729. Here the positions are reversed in that the Utah Consolidated company alleges wrongful extraction by the Utah Apex of ore in the Yampa limestone bed, the orebodies in controversy being indicated by the stopes above and below the Apex 1300-foot level. The plaintiff had mined a foot-wall vein which follows the contact between the limestone and the underlying quartzite; the contention was again made that the limestone forms a thick lode; it was argued that any orebodies within its limits are part of the lode. The Utah Apex conceded the ownership of the Yampa foot-wall vein, but denied any geologic connection between this vein and detached orebodies in the overlying limestone. We have not printed the decision of the Court in this case, since the conclusions are reached by much the same line of reasoning. The Utah Consolidated company, since the announcement of the decision, has voluntarily discontinued mining the Leadville orebodies, and its engineers are now engaged in calculating the value of the ore wrongfully removed. This estimate will be subject to exception by the Utah Apex company, in which event the Court will be called upon to determine the amount of damage.

The Divining Rod

By way of introduction, we may say that a few days ago a man called at this office to ascertain where he could buy a divining rod, which he wanted for use in finding some buried gold near Vallejo, at the northern end of the Bay of San Francisco. He was shown the proof of the article by William Pryce, appearing in this issue, and he asked particularly for the drawing given by the old Cornishman because he intended to make a divining rod for himself.

On another page we publish an excerpt from that remarkable old book, 'Mineralogia Cornubiensis', by William Pryce, of Redruth. This book, which is the 'Agricola' of Cornwall, was published in 1778 and is full of genuine information on mining affairs. Among other subjects discussed by Dr. Pryce is the divining rod, to which he gives the larger part of a chapter headed, 'Of the various Methods of discovering Mines'. His remarks on

the *virgula divinatoria* are full of good sense. He is "well convinced of its absolute and improveable virtues", but he does not undertake to decide upon the properties attributed to it, especially as he has found by trial that it does not work when in his own hands. However, it does extraordinary things when in the hands of friends whom he knows to be men of integrity, and not at all likely to deceive either themselves or others, so he is prepared to take it seriously. He finds that it works with some and not with others; it gives qualitative results but not quantitative; "it has been found to dip equally to a poor lode and to a rich one". The old Doctor tells us how his friend Mr. Cookworthy "satisfied the curiosity of some gentlemen" by finding "a lode that had been wrought" and by tracing another lode from a sea-cliff inland. Thirty years ago we had such a friend, who wielded the divining rod or forked stick of enchantment; he was Charles Latimer, the president of a Cleveland mining company, an old gentleman without guile. The Foxhall tunnel in Seaton mountain near Idaho Springs had cut a number of veins; we took Mr. Latimer into the tunnel, or adit, and arranged that he should walk ahead with the rod in the dark along the track and indicate the various veins as he came to them. He did. Later we hid a bunch of keys, a piece of copper, and a lump of galena in different parts of a room; he found them and labeled them iron, copper, and lead. Like Pryce, he had no explanation to offer. The various theories propounded by the old Cornish worthy are just about as intelligible as those advanced in these later days. We moderns talk about electric currents instead of effluvia, we use the modern jargon in place of the medieval, but we are no nearer the secret. Authentic accounts of the finding of water by 'dowsers', as the wielders of the rod are sometimes called, are numerous, and that the rod in the hands of some people will perform strange antics, there is no doubt. Like Hamlet, we conclude that there are more strange things in this world than are dreamt of in our philosophy.

The occult survives in contraptions even more dubious than the divining rod. We read recently of a gentleman at Haileybury, in Ontario, who owns an instrument "for locating the presence of the precious metals". He was being backed by a New York syndicate for the purpose of finding the treasures hidden by Captain Kidd on the Cocos islands. Mr. Andrew B. Cullen, this new diviner, had made demonstrations at Cobalt that had aroused "a moderate amount of curiosity" and there were "those among the prospecting fraternity who appear to believe that the instrument has some merit". It works "on the principle that affinities attract each other, and that by the proper use of a small piece of gold the instrument will point out the location of an ore deposit or hidden treasure containing gold". Another diviner appeared three months ago at San Antonio, Texas. His name is Professor L. V. J. Kimball. We read in the 'San Antonio Express' that his method likewise is based on "the principle of affinity". Orebodies containing gold and silver can be located, says he, "by use of magnetic needles of the proper affinity to within a few inches of their posi-

tion in the earth". In searching for "the chemical that would respond to gold" he has discovered the affinities that answer to 75 other substances. The Professor worked in the mines of California and "became disgusted with geology", because its methods were so uncertain. So he set to work and made the discovery that led to the invention of his 'finder'. It is a battery, which is "purely magnetic and not electric". All mineral substances, he says, are magnetic. They throw off magnetism. He has learned how to insulate magnetism. That is the secret. Of course, he will not divulge his method. It will not work with everybody, "because some people are electric while others are magnetic". He has said something, has he not? His instrument will detect oil at 25 miles and gold at 8 to 10 miles "at the farthest". Even that is a considerable achievement. He can operate "while riding along in a railroad coach or an automobile". What a grand way of scouting for possible mines in the wide and expansive regions of our West! Professor Kimball will not sell his services to Wall Street. No, Sir! His eyes blazed with indignation as he told the highly intelligent reporter "of an offer of a fabulous fortune for his instrument, with a big annual salary attached, made by a big corporation which proposed to use him and his instrument solely for their own purposes and to deny the rest of mankind the benefit of it". Damned greedy of them, say we. However, the attachment of that "big annual salary" seems rather to spoil the story, for the "fabulous fortune" appears almost to suffice. Even in the Antipodes they have their little fakes. We read that "a considerable amount of local interest has been aroused by reports that a 'diviner' had located two large gold-bearing quartz reefs at Little Plains" in New South Wales. He traced them for six miles; but Mr. L. J. Jones, of the Geological Survey, was unable to find anything "in the nature of a quartz reef in the various outcrops examined". Mining operations failed to confirm the divination and local excitement has subsided, we are informed. The miners have returned to the dreary drudgery of digging as a means of search for the precious metal.

The alchemy of one age is the chemistry of another, so the divining rod of a former century may prove to be the forerunner of a scientific device for detecting the precious things hidden in the crust of the earth. For the present, however, we remain sceptical. Indeed if ever somebody does discover some 'Open Sesame' in the prospecting way, he will, we presume, keep his secret to himself or at most share it with one or two trusted friends. We suspect the owner of an ore-finding device just as soon as he advertises his willingness to find ore for other people, even at a price. As yet all these queer instruments, whether a forked twig or an electric apparatus, at their best are merely qualitative, they fail to distinguish between poor rock and rich mineral, that is, they show no economic sense, they confuse 'waste' with 'ore'. The inventors and exploiters of these devices remind us of an advertisement we saw long ago in a Cripple Creek newspaper; it offered the services of spiritism to find an orebody. Yet the advertiser's address was Poverty Gulch. That is where most of these gentry remain.

DISCUSSION

Minerals Separation in Chile

The Editor:

Sir—I have just read with great pleasure the testimony given by you before the Federal Trade Commission during the hearing of the complaint against the Minerals Separation companies. Let me, therefore, congratulate you for your admirable evidence and at the same time assure you that all the "sinister imputations" of Minerals Separation against your well-established reputation for straight and fair dealings or against your never-questioned honesty will not shake in the slightest the faith and regard that the subscribers of the 'Mining and Scientific Press' have for you. As one of them, I protest strongly against such insinuations; though they are only degrading to those who make use of them.*

I have always followed with great interest your long, courageous, and praiseworthy campaign in the 'Press' against the mean and underhand methods of Minerals Separation, by which they have mainly endeavored to stifle and suppress the dissemination of all knowledge relating to flotation and to obtain an absolute monopoly over everything that relates to a process to the discovery and improvement of which they were, as you justly believe, only contributors.

I am sure it will be of interest to you to know what Chilean mining men think of Minerals Separation.

Señor Gandarillas Matta, the president of the society, in his address said that he wished to call attention to a subject of great importance to the mining industry, about which he had received several protests from responsible mining men. He referred to a notice published lately, about a petition which the Minerals Separation company had made to the Government asking for an extension of another 20 years to exploit in Chile their patents covering the concentration of ores by flotation.

"The Sociedad Nacional de Minería," he said, "must take notice of the danger which such a petition entails to the copper-mining industry."

All the members of the committee were in accord in the necessity of preventing "by all the means at their command" the continuance of such a state of things in Chile for another twenty years.

The sending of a resolution to the Minister for Industries was approved, explaining the situation, accompanied by the complete vote of the American Mining Congress, and asking the Minister to refuse to grant the extension asked for by Minerals Separation.

The text of the resolution sent to the Minister for Industries was published, together with the vote of the American Mining Congress, by the 'La Union' of Santiago and the 'La Nacion' of Valparaiso, as follows:

"The committee in their last meeting approved the calling of your attention to a notice published lately in the press of this capital which, if it were true, entails very grave danger to the copper industry of the country.

"According to this notice the Minerals Separation company has asked the Government to extend for 20 years more the right to exploit in this country their patent-rights covering their systems of concentrating ores by flotation.

"This notice, which may pass unperceived by the public, is, however, of enormous importance, which is the duty of the Sociedad Nacional de Minería to bring forward.

"The Minerals Separation company owns the patent-rights of concentration by flotation, which is the only one commercially applicable to the majority of Chilean copper deposits.

"The large low-grade deposits would yield a small profit per ton if treated by this system, and their owners could work them upon a more or less sure basis, by treating large masses that today have only a relative value.

"The Minerals Separation company has received for many years the benefit of their patents and in Chile itself has been receiving by their use about £50,000 per annum. In this the company has been protected by their patents, from the legal point of view, but has used objectionable methods in the giving out of licenses. The license agreements to which the licensees are subjected are truly despotic and one-sided (*leoninos*) not only on account of the high dues demanded but also because of all kinds of obstacles and severe conditions imposed.

"We will not allow the truth of these assertions to rest solely on ourselves, but will quote in our behalf an authority of world-wide reputation in this matter.

"The American Mining Congress is an institution that meets annually in the United States with the assistance of delegates from all the mining States, together with the most distinguished mining engineers and business men connected with mining enterprises. This Congress, in its meeting of the 21st of November 1919, at St. Louis, unanimously approved the following vote. [The translation into Spanish of the vote follows.]

"If such has been the conduct of the Minerals Separation company in the United States, you will understand that there has been no reason to make it more gentle in Chile.

*Allowance must be made for the charming exaggerations Spanish custom. The 'caballero' makes us blush.—Editor.

"And if such has been the condemnation that its monopolistic policy has merited, we can see no reason why we should allow it legally to continue to exercise it here for another 20 years.

"The rights of the inventor have already been well paid for and what up to now has been a legal reward to the discoverer of the process would become an irritating monopoly that no legislation can sanction.

"The royalty of six pence per ton which up to now Minerals Separation has been charging is without a doubt very high, but has been accepted as a tribute to the intelligence of the discoverer, under the protection of the law.

"But there must be a limit to this. In so essentially a mining country as Chile, where the future of the copper-mining industry is so closely connected to the exploitation of low-grade deposits, flotation is absolutely indispensable and must be declared a public utility.

"For these reasons we ask, that when the opportune moment arrives, your high influence be used so that the original patents of Minerals Separation be declared expired and that under no pretext will new privileges be conceded to this company in this country."

Let us hope that the Chilean Minister for Industries takes the advice of the Sociedad Nacional de Minería and refuses to extend for another 20-year period the patent-rights of Minerals Separation in Chile. If so, the first complete victory against the soulless patent-exploiting combination may be said to have been won; and no small credit for it will be due to you, Mr. Editor.

Santiago, Chile, September 23.

INGENIERO.

Two Suggestions on a National Problem

The Editor:

Sir—In reply to the letter by M. W. von Bernewitz in your issue of October 16, he seems to take the stand that he may draw inferences from my letter, but that I must not do so from his. He appears to be under the impression, too, that my letter was antagonistic to his, whereas, of course, it was not intended to be anything of the kind. His letter simply formed an incentive to air my own views on the subject.

I freely admit that I did infer from his letter in your issue of August 14 that Mr. von Bernewitz considered the method of storing gas on automobiles in England during the War was a stupid method, and admittedly it would have been a stupid method had there not been an excellent reason for it, as I stated in my letter of September 11. Mr. von Bernewitz said: "According to Captain Brewer, who addressed the engineering societies in San Francisco a couple of years ago, during the War, some automobiles in England used city gas, which was stored in an unsightly bag atop of the machine. This gas was at low pressure, supplied by gas-works. My suggestion is to compress the gas to several hundred pounds, store it in a receiver on the machine, and pass it through a reducing-valve before use." The storage of gas at high pressures (often several thousand pounds)

for many purposes has been such a common practice in England for so many years that Mr. von Bernewitz by his suggestion did seem to me to imply stupidity that it was not done, and I think it probable that many others made the same inference. Once again, I did not intend to convey the impression that Mr. von Bernewitz thought the fuel situation cause for panic. I simply said that I did not, though I considered it serious.

Mr. von Bernewitz was justified, perhaps, in making the inference that I thought he was advocating the use of producer-gas for raising steam, though I did not say so. I should have worded the sentence a little differently, and then would have avoided the ambiguity. Producer-gas has been, and is, used in Europe for raising steam, and there was justification for such use before the fixation of nitrogen from atmospheric air had been accomplished, and before the improvement in methods of burning finely pulverized fuels. More ammonia is obtained from the fuel when converted into producer-gas than by any other method, and this to some extent relieved the immense drain that was being made on the nitrate deposits of the Tarapaca and Tacoma valleys, in Chile and Peru. With improved methods of burning pulverized fuel, allowing many low-grade fuels to be used, there does not seem to be the same justification for the use of producer-gas for raising steam.

Notwithstanding its use in Europe, the employment of a gas containing 60% of inert matter as an internal-combustion-engine fuel does not appeal to me as good practice, especially when we consider that for every volume of oxygen used for its combustion four volumes of nitrogen has to be introduced, making the total amount of inert material rather appalling. Some day, if Dr. Cottrell's dream of the use of oxygen materializes, and there seems to be no reason why it should not, this may not be necessary.

The increased use of the internal-combustion engine has been so rapid that it entirely has overtaken the production of suitable fuels for its operation. These, I believe, will come in time. In the meantime, anything that will help to solve the problem is of national importance, and I have no desire to decry the use of producer-gas, or anything else, that is likely to bring relief. We see things from different angles, however, and thoughtful discussion should produce good. As an illustration of how widely sometimes those angles diverge, I was interested to read in an industrial chemical journal recently condemnation of attempts to make alcohol for motor-fuel synthetically from acetylene, on the ground that if, instead of converting the calcium carbide into acetylene, it were converted into nitrolime, or calcium cyanamide, and utilized as a fertilizer the increase in the production of grain would be capable of making four times the amount of alcohol that could be made directly from the carbide. As to the accuracy of this, I know nothing. The agricultural part is outside my line of thought. There is, however, a great field open to the industrial chemist in the manufacture of alcohol from waste products.

Victoria, B. C., October 23.

F. H. MASON.

Utah Apex v. Utah Consolidated; Abstract of the Court's Opinion

The parties to this action are corporations engaged in the business of mining. They own adjoining properties in Bingham, a mining camp situated a few miles southwest of Salt Lake City, in this State. Certain of the mining claims of the plaintiff lie north of and adjacent to certain of the mining claims of the defendant. Prior to the commencement of this action the defendant had entered beneath the surface of the adjacent claims of the plaintiff and began to remove and appropriate valuable ores and mineral found therein. By this action the plaintiff seeks to enjoin further entry by the defendant within the premises of the plaintiff and the removal of the ores and mineral therein, and for an accounting.

The defendant in its answer admits that it has entered beneath the surface of the mining claims owned by the plaintiff, and that it has removed, and will continue to remove, the ores and mineral found therein, and justifies its action in so doing on the ground that the ores and mineral beneath the surface of the plaintiff's property are within a broad lode apexing within the boundaries of the mining property of the defendant, and that the said ores and mineral found within said lode beneath the surface of the mining property of the plaintiff belong to and are the property of the defendant by virtue of the extra-lateral rights conferred by the laws of the United States in such cases.

Geologically the country involved in this litigation consists of an underlying quartzite bed or stratum of unknown extent and thickness. Upon this quartzite there is a limestone bed, called the Highland Boy limestone, of an average thickness of about 250 ft., but varying in thickness from about 100 to 400 ft. Above the Highland Boy limestone there is a bed of quartzite having an average thickness of about 250 ft., and above this quartzite bed there is another limestone bed, called the Yampa limestone, with an average thickness of about 200 ft., but varying in thickness from a few feet at or near the surface to 400 or 500 ft. at depth in the neighborhood of the steepening of the dip of the limestone. Above the Yampa limestone there is a quartzite stratum having a thickness of about 700 ft., and above this stratum of quartzite a limestone bed, called the Parnell, of about 30 ft. in thickness. Upon the Parnell limestone rests a quartzite bed containing within it here and there thin lenses of limestone. This bed of quartzite has a thickness of about 80 ft. Above this quartzite there is a thin bed of limestone called the Petro, and above the Petro an indefinite thickness of quartzite in which are found here and there thin lenses of limestone.

The limestone and quartzite beds above mentioned are sedimentary rocks and, as laid down in the bottom of the sea, were originally level. Later and in the mountain-

making of this region these sedimentary beds were uplifted and more or less tilted and bent so that now they have a dip northerly at the surface and for some considerable distance below the surface of about 30°, and an easterly and westerly strike across the country.

Subsequent to the mountain-building which resulted in the tilting of these sedimentary beds of limestone and quartzite there was an intrusion of porphyry—an igneous rock coming up from the depths, apparently from the south and east—which cut through, absorbed or threw aside portions of the sedimentary beds of limestone and quartzite lying above. After this intrusion of porphyry the ores and mineral contained in the mining properties of the parties to this action were deposited.

The ores and mineral in controversy in this action are found beneath the surface of the mining claims of the plaintiff in the Highland Boy limestone and only to a limited extent in the quartzite above or below it. The outcrop or apex of the Highland Boy limestone is within the boundaries of mining claims owned by the defendant. On its dip to the north the Highland Boy limestone passes beneath the surface of the mining claims of the plaintiff where, as already stated, the disputed ores and mineral are located which in the testimony are called the Leadville orebody and the locality spoken of as the Leadville country.

The Leadville orebody is a relatively narrow (as compared with the various other orebodies involved in this series of litigation) and practically continuous body of ore extending about 2000 ft. in a north-easterly and south-westerly direction along the course of what has been variously spoken of by the witnesses as a fault, a fault-fissure, a fissure, a fissure-zone, a fissure-vein. The ore is a lead ore found east of the fissure making out into the limestone.

Up the dip of the Highland Boy limestone about one-fourth of a mile from the Leadville orebody there has been developed and mined an immense deposit of ore. This deposit was made up of a great number of closely associated and related orebodies almost entirely in the limestone and extending in length for a distance of approximately 3000 ft. in a north-easterly direction, roughly paralleling the Leadville orebody, and from 200 to as much as 1000 ft. in width. All of these orebodies were copper ore except a few found near the surface, which were lead.

The maps and models introduced in evidence by the parties show more clearly than words can describe a great mass of porphyry adjacent to and lying south of and below the outcrop of the Highland Boy limestone in the mining claims of the defendant.

There is also shown upon the maps and models down

the dip of the Highland Boy limestone a comparatively narrow sheet and fingers of porphyry extending up and cutting through the Highland Boy limestone above and north of the orebodies above described, with one or two exceptions, and inclosing between this sheet and fingers of porphyry and the great mass of porphyry lying south of and below the apex of the limestone the segment of the Highland Boy limestone in which these orebodies were deposited.

This great deposit, lying south of and below the sheet and fingers of porphyry, is admitted by the plaintiff to be a broad lode.

At this time I will say I do not think the admission of counsel for plaintiff, made in his opening statement, that plaintiff conceded the orebody bounded on the foot-wall side by quartzite and porphyry, and on the hanging-wall side by the sheet and fingers of porphyry above mentioned, was a broad lode, or the testimony of plaintiff's witnesses to the same effect, shifted the burden of proof.

Lying between this admitted broad lode and the Leadville orebody is a body of the Highland Boy limestone of about 250 ft. in thickness and extending north-easterly about 2000 ft. and north-westerly about 1400 or 1500 ft. This intervening limestone has been explored only to a very limited extent. Five or six years ago the defendant ran a drift on the 1300 level westerly from the vicinity of the main shaft of its upper mine through the Highland Boy limestone, a distance of about 1800 ft., to an intersection with the Leadville fissure. This drift was continued westerly and north-westerly several hundred feet through the limestone and overlying quartzite to the Yampa limestone. It was at this time that the Leadville ores were discovered by the defendant. The subsequent mining and removal of these ores have occasioned this lawsuit.

After the discovery of the Leadville orebodies the defendant ran a cross-cut from the 900 level of its upper mine through the limestone westerly down and into the Leadville country. More recently it has run a drift on its 1600 level, from the vicinity of the main shaft of the upper mine, through the limestone to the Leadville country. There is also a cross-cut from the 700 level of the upper orebody through the Highland Boy limestone and the overlying quartzite to the Yampa limestone. In addition to these drifts and cross-cuts run into and through the limestone intervening between the upper and Leadville orebodies, there are numerous drifts and cross-cuts from the main workings of the upper mine, and a few drifts and cross-cuts from the main workings of the Leadville orebody extending a comparatively short distance into this intervening limestone.

A glance only at the maps and models of the parties makes it manifest that this intervening country is undeveloped and unprospected. The drifts and cross-cuts into and through the intervening limestone above the drift on the 1300 level show the limestone to be unmineralized, in the main unaltered, and but slightly fissured or broken as compared with the limestone found in the

upper or the Leadville orebodies. Indeed this is admitted by the defendant in its brief. It is stated:

"In this area of little development, its upper portion is correctly described as unaltered barren limestone."

In the drift upon the 1300 level there is a slight showing of mineral at two or three places, and also some fissuring along the drift. In the drift upon the 1600 level there are more evidences of mineralization and the rock is more extensively altered and fissured. There is mineralization found in this drift in the neighborhood of the Leadville fissure which may be, and probably is, connected with the Leadville orebody. There is also mineralization and a little ore found further to the east in this drift and referred to in the evidence as Litigation stope. This mineralization has not been developed sufficiently to determine its value or its connection, if any, with either the upper orebody or the Leadville orebody.

It is the contention of the defendant, based upon numerous considerations, that this undeveloped body of the Highland Boy limestone is good prospecting ground in which the miner may work with reasonable expectation of finding ore anywhere, and that it is a part of the broad lode as conceded by the plaintiff. In other words, it is the contention of the defendant that the Highland Boy limestone, outcropping upon the mining claims of the defendant and extending on its dip beneath the surface of the claims of the plaintiff, is one broad lode. The plaintiff controverts these contentions of the defendant and asserts that this undeveloped limestone is a body of barren limestone breaking the continuity of the upper orebodies and clearly constituting an area of separation between the two orebodies, and, in addition, maintains that the porphyry sheet and fingers above and overlying the orebodies, admitted by it to be a broad lode, constitute the north boundary of the lode.

Our first consideration, then, is: What constitutes a lode within the meaning of the statute? What are its characteristics and nature? What its extent, its limits, and boundaries?

"The locators of all mining locations heretofore made or which shall hereafter be made, on any mineral vein, lode, or ledge, situated on the public domain, their heirs and assigns, where no adverse claim exists on the tenth day of May, eighteen hundred and seventy-two, so long as they comply with the laws of the United States, and with state, territorial, and local regulations, not in conflict with the laws of the United States governing their possessory title, shall have the exclusive right of possession and enjoyment of all the surface included within the lines of their locations, and of all veins, lodes, and ledges throughout their entire depth, the top or apex of which lies inside of such surface lines extended downward vertically, although such veins, lodes, or ledges may so far depart from a perpendicular in their course downward as to extend outside the vertical side-lines of such surface locations. But their right of possession to such outside parts of such veins or ledges shall be confined to such portions thereof as lie between vertical

planes drawn downward, as above described, through the end-lines of their locations, so continued in their own direction that such planes will intersect such exterior parts of such veins or ledges. And nothing in this section shall authorize the locator or possessor of a vein or lode which extends in its downward course beyond the vertical lines of his claim to enter upon the surface of a claim owned or possessed by another."

The defendant cites the Eureka case, 4 Sawyer 302, 311, 8 Federal Cases (No. 4548), and urges with great earnestness that the facts of that case are so nearly analogous to the facts in the case at bar that no other conclusion is possible than that the Highland Boy limestone constitutes the lode, as the zone of limestone was found to be the lode in that case.

The defendant not only urges the similarity of con-

eral miles in length, running in a northerly and southerly course. Adjoining its northerly end is this spur called Ruby Hill, which extends thence westerly, or in a south-westerly direction. Along and through this hill, for a distance slightly exceeding a mile, is a zone of limestone, in which, at different places throughout its length, and in various forms, mineral is found, this mineral appearing sometimes in a series of succession of orebodies more or less closely connected, sometimes in apparently isolated chambers, and at other times in what would seem to be scattered grains."

After discussing at some length the statute and the definition of a lode within the meaning of the statute, he proceeds:

"Examining, now, with this definition in mind, the features of the zone which separate and distinguish it

FIG. 1. GEOLOGIC SECTION SHOWING LEADVILLE OREBODIES

ditions as deduced from the statement of facts found in the opinion, but relied upon testimony of witnesses called by it who testified that the conditions existing in the two mines were similar, one of whom had recently been in a portion of the Eureka mine and who testified to his observations. Inasmuch as this testimony was received during the progress of the trial and is commented upon by counsel for the defendant in argument, it is only fair to say that the weight which I shall give to the Eureka case as an authority will be based upon the facts stated in the opinion. The testimony of witnesses conflicting with the facts stated in an opinion cannot, in my judgment, either enlarge or limit the authority of the opinion in another case before another court. Upon the facts stated in the opinion, the Eureka case is a most valuable one for our consideration in this case, and requires more than passing notice. Judge Field, who wrote the opinion, in respect to the facts said:

"The mining ground which forms the subject of controversy is situated in a hill known as Ruby Hill, a spur of Prospect mountain, distant about two miles from the town of Eureka, in Nevada. Prospect mountain is sev-

eral miles in length, running in a northerly and southerly course. We find that it is contained within clearly defined limits, and that it bears unmistakable marks of originating, in all its parts, under the influence of the same creative forces. It is bounded on the south side for its whole length, at least so far as explorations have been made, by a wall of quartzite of several hundred feet in thickness; and on its north side, for a like extent, by a belt of clay, or shale, ranging in thickness from less than an inch to 70 or 80 ft. At the east end of the zone, in the Jackson mine, the quartzite and shale approach so closely as to be separated by a bare seam, less than an inch in width. From that point they diverge, until, on the surface in the Eureka mine, they are about 500 ft. apart, and on the surface in the Richmond mine, about 800 ft. The quartzite has a general dip to the north, at an angle of about 45°; subject to some local variations, as the course changes. The clay or shale is more perpendicular, having a dip at an angle of about 80°. At some depth under the surface, these two boundaries of the limestone, descending at their respective angles, may come together. In some of the levels

worked, they are now only from two to three hundred feet apart.

"The limestone found between these two limits—the wall of quartzite and the seam of clay or shale—has, at some period of the world's history, been subjected to some dynamic force of nature, by which it has been broken up, crushed, disintegrated, and fissured in all directions, so as to destroy, except in places of a few feet each, so far as explorations show, all traces of stratification; thus specially fitting it, according to the testimony of the men of science, to whom we have listened, for the reception of the mineral which, in ages past, came up from the depths below in solution, and was deposited in it. Evidence that the whole mass of limestone has been, at some period, lifted up and moved along the quartzite, is found in the marks of attrition engraved on the rock. This broken, crushed, and fissured condition pervades, to a greater or less extent, the whole body, showing that the same forces which operated upon a part, operated upon the whole, and at the same time. Wherever the quartzite is exposed, the marks of attrition appear. Below the quartzite no one has penetrated. Above the shale the rock has not been thus broken and crushed. Stratification exists there. If in some isolated places there is found evidence of disturbance, that disturbance has not been sufficient to affect the stratification. The broken, crushed, and fissured condition of the limestone gives it a specific individual character, by which it can be identified and separated from all other limestone in the vicinity.

"In this zone of limestone numerous caves or chambers are found, further distinguishing it from the neighboring rock. The limestone being broken and crushed up as stated, the water from above readily penetrated into it, and, operating as a solvent, formed these caves and chambers. No similar cavities are found in the rock beyond the shale, its hard and unbroken character not permitting, or at least opposing such action from the water above.

"Oxide of iron is also found in numerous places throughout the zone, giving to the miner assurance that the metal he seeks is in its vicinity.

"This broken, crushed, and fissured condition of the limestone, the presence of the oxides of iron, the caves or chambers we have mentioned, with the wall of quartzite and seam of clay bounding it, give to the zone, in the eyes of the practical miner, an individuality, a oneness as complete as that which the most perfect lode in a geological sense ever possessed. Each of the characteristics named, though produced at a different period from the others, was undoubtedly caused by the same forces operating at the same time upon the whole body of the limestone.

"Throughout this zone of limestone, as we have already stated, mineral is found in the numerous fissures of the rock."

Then after discussing the opinions of the expert witnesses, he concludes:

"Our judgment being that the limestone zone in Ruby Hill, in Eureka district, lying between the quartzite and

the shale, constitutes, within the meaning of the acts of Congress, one lode of rock-bearing metal, we proceed to consider the rights conveyed to the parties by their respective patents from the United States."

* * * * *

It is evident that the Eureka company claimed that the limestone constituted one lode, upon facts substantially as the court states them to be in the opinion. On the other hand, it is evident the Richmond company maintained that the ores found in the limestone constituted several lodes. It is stated in the opinion that:

"According to the opinions of all the scientific men who have been examined, this mineral was brought up in solution from the depths of the earth below, and would therefore naturally be very irregularly deposited in the fissures of the crushed matter, as these fissures are in every variety of form and size, and would also find its way in minute particles in the loose material of the rock."

It is stated that the expert witnesses called by the Eureka company all gave it as their opinion that the limestone constituted a vein or lode in the sense in which those terms are used by miners, and the language of Dr. Hunt, one of the witnesses for plaintiff, is quoted with evident approval in the opinion:

"That this whole mass of rock is impregnated with ore; that although the great mass of ore stretches for a long distance above horizontally and along an incline down the foot-wall, as I have traced it, from this deposit you can also trace the ore into a succession of great cavities or bonanzas lying irregularly across the limestone and into smaller caverns or chasms of the same sort; and that the whole mass of the limestone is irregularly impregnated with the ore. I use the word 'impregnation' in the sense that it has penetrated here and there; little patches and stains, ore-vugs and caverns and spaces of all sizes and all shapes, irregularly disseminated through the mass. I conclude, therefore, that this great mass of ore is, in the proper sense of the word, a great 'lode', or a great 'vein', in the sense in which the word is used by miners; and that practically the only way of utilizing this deposit, is to treat the whole of it as one great ore-bearing lode or mass of rock."

* * * * *

Summarizing the facts found by the Court in the Eureka case: There was a wedge-shaped zone of limestone dipping into the mountain for a distance slightly exceeding a mile lying between quartzite and shale beds which at the east end of the zone approach so closely as to be separated by a bare seam less than an inch in width. From that point they diverged until on the surface in the Eureka mine they were about 500 ft. apart, and on the surface in the Richmond mine about 800 ft. In this limestone zone at different places throughout its length and in various forms, mineral was found, sometimes in a series or succession of orebodies more or less closely connected, sometimes in what would seem to be scattered grains. This limestone zone was broken up, crushed, disintegrated, and fissured in all directions so as to de-

stroy, except in places of a few feet each, so far as exploration showed, all traces of stratification.

Evidence that the whole mass of limestone had been at some period lifted up and moved along the quartzite was found in the marks of attrition engraved on the rock. This broken, crushed, and fissured condition pervaded, to a greater or less extent, the whole body, showing that the same forces which operated upon a part operated upon the whole at the same time.

The broken, crushed, and fissured condition of the limestone gave it a specific, individual character by which it could be identified and separated from all other limestone in the vicinity. In the zone of limestone numerous caves or chambers were found, further distinguishing it from the neighboring rock. The limestone being broken up and crushed, as stated, the water from above readily penetrated into it and, operating as a solvent, formed these caves and chambers. No similar cavities were found

in this case. In the Eureka case there were not two orebodies separated by a quarter of a mile of comparatively unbroken, unchanged, and unmineralized limestone, one of them upon a fissure, if not a true fissure-vein, as in the Leadville orebody in this case. Nor was there an intrusion of porphyry from below practically inclosing one of the orebodies on the hanging-wall side, as in this case.

In view of the facts in the Eureka case and the issues made by the parties, it is not astonishing that Judge Sawyer, who sat in the Eureka case with Justice Field, in the Mount Diablo case, 17 Fed. Cas. (No. 9886) 918, said:

"It never was intended in that case (the Eureka case) to hold that every metalliferous zone of country, to which boundaries could be found, must be regarded as one vein or lode, for this would be to reduce all mining districts to one lode."

I conclude, therefore, that the Eureka case is authority

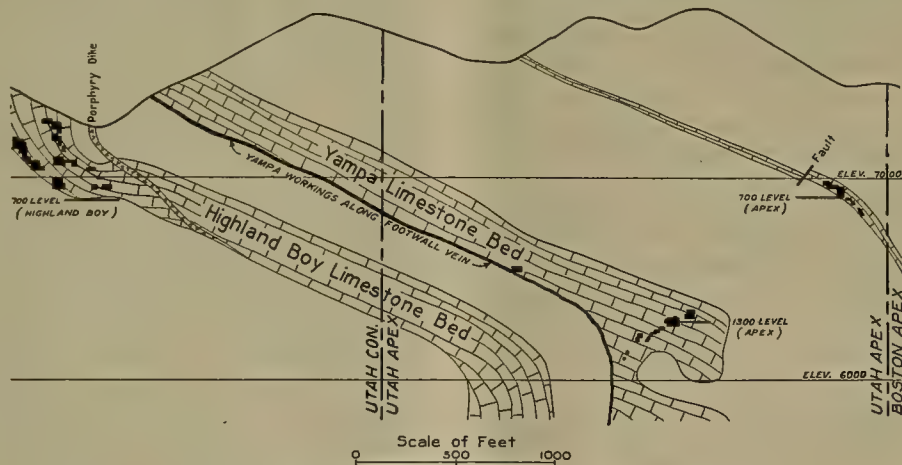

FIG. 2. GEOLOGIC SECTION SHOWING YAMPA OREBODIES

in the rock beyond the shale, its hard and unbroken character not permitting, or at least opposing such action from the water above.

Oxide of iron was also found in numerous places throughout the zone, giving to the miner assurance that the metal he sought was in its vicinity.

This broken, crushed, and fissured condition of the limestone, the presence of the oxides of iron, the caves or chambers, the wall of quartzite and seam of clay bounding it, gave to the zone, in the eyes of the practical miner, an individuality, a oneness as complete as that which the most perfect lode, in a geological sense, ever possessed. Each of the characteristics named, though produced at a different period from the others, was undoubtedly caused by the same forces operating at the same time upon the whole body of the limestone.

Throughout this zone of limestone mineral was found in the numerous fissures of the rock.

The facts which distinguish the case at bar from the Eureka case are so numerous and distinctive that I have no hesitancy in saying that the decision of the Court in the Eureka case upon the facts there found to exist cannot be held to be controlling under the facts as they exist

for finding that the upper orebody found in the Highland Boy limestone, developed on its plunge and rake in the limestone, is a lode or vein within the meaning of the statute. Authority requiring the inclusion of the Leadville orebody and the intervening limestone in this upper lode, or justifying the calling of the entire Highland Boy limestone a lode, must be found in some other case.

The case of United States Mining Company v. Lawson, 134 Federal, 769, decided by the Circuit Court of Appeals of this circuit, is confidently relied upon by counsel for the defendant as such a case.

The orebodies which were the subject of litigation in the Lawson case were found in a body of limestone called the Jordan limestone, separated only a few thousand feet from the Highland Boy limestone, and as the Jordan limestone and the Highland Boy limestone are undoubtedly a part of the same sedimentary bed, uplifted at the same time, and possibly mineralized from the same mass or similar masses of porphyry lying below, it is incumbent upon me to give the decision of the case by the Circuit Court of Appeals most thoughtful consideration.

Counsel for the defendant have urged that I should

read and consider the record in that case in connection with the opinion of the Court. I have read the briefs in the Lawson case, filed in the Supreme Court of the United States, which contain more or less extended excerpts of the testimony of various witnesses of the parties. It is only fair to say, however, that I did not read the briefs for the purpose of forming an opinion upon the merits of the case but to learn the theory held by the respective parties as to the law applicable to the case, and to learn what each claimed the evidence proved.

Justice Van Dervanter has admirably stated the contentions of the parties in his statement of the case in the following language:

"The evidence was chiefly directed to the question whether or not the stratum of limestone constitutes a single broad vein or lode of mineral-bearing rock. Complainant insisted, and its evidence tended to show, that this stratum is such a single vein or lode, while the defendants insisted, and their evidence tended to show, that the stratum embraces several distinct and independent veins or lodes; that one such vein or lode, called a 'bedded vein', has its apex within the surface lines of the Kempton, extends on its strike in the direction of the Kempton end-lines, passes on its dip beneath the surface beyond the northerly side-line of that claim, and through the Jordan Extension, Ashland, Northern Light, Grizzly, and Fairview; that another distinct and independent vein or lode, called the 'Ashland cross-fissure', and of which the bedded vein is claimed to be a lateral continuation or appendage, has its apex in the Ashland, passes on its dip beneath the surface beyond the northwesterly side-line of that claim, and through the Northern Light, Grizzly, and Fairview, and that the orebodies in controversy are parts of the two veins or lodes, the apices of which are within the Kempton and Ashland."

From the foregoing statement it is seen that the evidence introduced by the defendants tended to show that the limestone embraced two distinct veins or lodes, namely, the Kempton vein and the Ashland cross-fissure, while in the Eureka case the evidence of the defendant, the Richmond company, did not tend to show the existence of one or more distinct or independent veins or lodes, but was directed to what the defendant and its witnesses defined to be or not to be a vein or lode. The decision of the Eureka case upon the admitted facts, was a question of law; the decision in the Lawson case one of fact.

The Court in the body of the opinion in the Lawson case says:

"A careful examination and consideration of the evidence clearly convinces us that the stratum of limestone constitutes a single broad vein or lode of mineral-bearing rock extending from the quartzite on one side to the quartzite on the other. The limestone has been profoundly broken, altered, and mineralized, and has thereby obtained an individuality, which, apart from other differences, clearly distinguishes it from the neighboring rock. There is a local absence of ore in places, a con-

tinuous occurrence of it in others, and a seeming local occurrence of it in still others, but the orebodies are not separated, one from another, by any definite boundaries. As in Eureka Consolidated Mining Co. v. Richmond Mining Co., 8 Fed. Cas. 819, 825 (No. 4548), they are parts of one greater deposit, which permeates, in a greater or less degree, with occasional intervening spaces of barren rock, the whole mass of limestone. As shown by extensive exploration and actual mining, the mineralization has been so general that its only defined limits are the quartzite walls which bound the limestone and within it one may reasonably expect to encounter ore by driving or cross-cutting in any direction.

"In addition to the many small fissures which exist only in the limestone and extend in every direction, other ore-bearing fissures of approximately a northerly and southerly direction are found in the quartzite, and it is the contention of the defendants that these extend through the limestone, and that its mineralization is due to them and occurred at the same time and in the same manner as did the deposition of the ore in them, and that the orebodies in the limestone are lateral continuations or appendages of these cross-fissure veins. Of this it is sufficient to say that, whatever may have been the mineralizing process, the alteration and mineralization of the limestone were so general and extensive as to convert it into a single broad vein or lode within which the cross-fissure veins are without defined boundaries, and so far lose their identity that they cannot be distinguished from the larger orebodies therein. The ore in the quartzite is inconsiderable in amount, and is confined to these fissure-veins, but it is not so in the limestone. In the evidence for the defendants it is conceded that there are no walls separating the cross-fissures from the bodies of ore in the limestone; but it is attempted to be shown that the ore in the fissures, and especially in the Ashland fissure, is distinguishable because its lamination conforms to the strike and dip of the fissure, while the lamination of the ore on either side conforms to the strike and dip of the limestone. We think the evidence for the defendants, as well as that for the complainant, shows that the difference in the lamination is not always discernible, and is an uncertain and unreliable test of the extent and boundaries of the cross-fissures. To illustrate, Mr. Wall, one of the defendants, says the plating of the ore in the limestone is similar in appearance to that of the ore in the fissure where the orebodies are large and wide, but a considerable distance from the fissure the structural lines become distinct and parallel to the bedding of the limestone. Mr. Legg, a witness for the defendants, says there is no sharp line of division, and the fissure structure and the influence of the fissure extend for considerable distances from the original fissure. Mr. Neill, another of the defendant's witnesses, says the fissure is entirely destroyed in places within the orebodies in the limestone. Mr. Moorehouse, also a witness for the defendants, says the Ashland fissure has a width in the quartzite of not exceeding three feet, and, when measured by the difference in the lamination of the ore,

has a width in the limestone of 180 ft. The defendants lay much stress upon the testimony of Mr. Holden, a witness for the complainant, who says: 'The Ashland vein can be followed for quite a distance into the Big Jordan (limestone) lode, and can be traced. It is like all of these fissures; it is somewhat difficult to follow through, but the way we do trace them we get a line from the quartzite on either side, or from one quartzite wall, and follow that line out, but we can't always find the limits of the fissure, which we take to be one of the cross-fissures.'

"This is far short of a statement that the boundaries of the Ashland, or of any other fissure, are well defined within the orebodies in the limestone. Particularly is this true when the entire testimony of the witness is considered, because he also says much of the limestone has been mechanically and chemically altered until the entire original stratification or bed structure has disappeared. Our conclusion upon this controverted question of fact is that the orebodies within the claimed spaces of intersection created by the cross-fissures, including the Ashland, are not susceptible of identification and separation from those in the stratum of limestone, and must be held to be parts of the single broad vein or lode and not parts of distinct and independent cross-fissure veins."

It is readily seen that the facts stated by the Court as above quoted do not run parallel to the facts in the case at bar. Here we have two orebodies, one a broad lode practically inclosed by a sheet and fingers of intruded porphyry, separated from the second orebody located upon a fissure as much as a fourth of a mile distant, with a mass of comparatively unbroken, unchanged, and unmineralized limestone intervening between them. Here there is no question of the ore found in one body extending into, overlapping, or joining with the ore of the other. While the ore extends for a considerable distance at places away from the Leadville fissure, the great mass of intervening limestone separates it from any of the orebodies of the broad lode above.

In the Lawson case the Court concludes its statement of the facts in the following language:

"Our conclusion upon this controverted question of fact is that the orebodies within the claimed spaces of intersection created by the cross-fissures, including the Ashland, are not susceptible of identification and separation from those in the stratum of limestone, and must be held to be parts of the single broad vein or lode, and not parts of distinct and independent cross-fissure veins."

In the case at bar there is no question of spaces of intersection between the broad lode above and the Leadville orebody below, created by cross-fissures or otherwise, and hence there is no question of identification and separation of the ores or orebodies found in the upper lode from the ore or orebodies found in the Leadville, and hence in this case the reason given in the quoted paragraph above does not exist upon which it was held in the Lawson case that all the ores found in the limestone were parts of a single broad vein or lode and not parts of distinct and independent cross-fissure veins.

* * * * *

In the case at bar we cannot say that the whole of the Highland Boy limestone has been profoundly broken, altered, and mineralized, and has thereby obtained an individuality which, apart from other differences, clearly distinguishes it from the neighboring rock.

On the contrary, in this case we have a large body of limestone lying between the two orebodies, comparatively unbroken, unaltered, and unmineralized.

In this case we cannot say, as was found by the Court in the Lawson case, that the orebodies are not separated, one from another, by any defined boundaries. On the contrary, in this case the orebodies are separated by the inclosing porphyry sheet and fingers and by the barren, unmineralized, and comparatively unbroken and unaltered limestone.

It has not been shown by extensive exploration or actual mining in the Highland Boy limestone that the mineralization has been so general that its only defined limits are the quartzite walls which bound the limestone, or that within it one may reasonably expect to encounter ore by driving or cross-cutting in any direction, as was found by the Court in the Lawson case. There has been only a limited exploration and no actual mining in the great mass of limestone lying between the two orebodies in the Highland Boy limestone. This limited exploration shows no mineralization above, and but slight mineralization below. If this condition of the limestone continues throughout its mass, the miner would not encounter ore by driving or cross-cutting in any part of it, whatever his expectations might be.

* * * * *

It cannot be said in this case that the ores of the Leadville orebody lose their identity, or that they cannot be distinguished from the orebodies found in the Highland Boy limestone above, as was found by the Court in the Lawson case to be the condition with respect to ores claimed by the defendants to belong to the Ashland fissure.

It was conceded in the Lawson case that there were no walls separating the cross-fissures from the bodies of ore in the limestone. In this case it is insisted with great earnestness that the porphyry sheet and fingers and intervening limestone constituted a definite, certain, and well-defined boundary separating the two orebodies.

On the other hand, in the Lawson case many of the facts are the same as, or similar to, the facts in this case. The orebodies which were the subject of litigation in the Lawson case were located only a few thousand feet from the orebodies which are the subject of litigation in this case. The Jordan limestone and the Highland Boy limestone are parts of the same sedimentary bed, and each lies between the same underlying and overlying quartzite. The sedimentary beds were subjected to the same forces by which they were uplifted and more or less tilted and bent as we now find them. In both, the sedimentary beds have been more or less broken and penetrated by masses of porphyry ascending from the deep. In both, the predominating minerals are copper and lead, found mainly

in the limestone, deposited there by replacement from solutions coming up from the masses of porphyry beneath. In the Lawson case the Court found the whole of the Jordan limestone to constitute one broad lode. In this case it is admitted that the upper segment of the Highland Boy limestone constitutes one broad lode. In both the Jordan and the Highland Boy limestones and the quartzite and other limestone beds lying above, are found numerous faults and fissures, some of them, as the Ashland in the Jordan and the Leadville in the Highland Boy, containing mineral. Except as heretofore noted, in both the limestone is similarly broken, altered, and mineralized.

The expert witnesses called by the defendant gave it as their opinion that the Highland Boy limestone intervening between the upper orebodies and the Leadville orebody may be prospected by the miner with reasonable expectation of finding ore by cross-cutting in any direction. It is the opinion of these witnesses that the Highland Boy limestone is one broad lode.

The expert witnesses for the plaintiff gave it as their opinion that the upper orebody below and south of the intruded sheet and fingers of porphyry is a broad lode, and that these porphyry intrusions constitute its northern boundary. It is the opinion of these witnesses that the Leadville orebody is a distinct entity, and that the intervening limestone is unmineralized and barren, and constitutes no part of either the upper lode or the Leadville orebody.

The experts called by the respective parties and who have testified in this case are men of great learning as geologists and of wide experience as mining engineers. I do not question the sincerity of any one of them. The opinion of each group commands attention and respectful consideration. So evenly are they balanced in learning and in experience that it would be difficult to determine on which side is the greater weight of the evidence, if it was not for the existence of an undisputed fact in the case confirming the opinion of the expert witnesses called by the plaintiff.

The witnesses for the defendant testified that this intervening limestone was ground in which the miner might reasonably expect to encounter ore by driving or cross-cutting in any direction. As stated by counsel of the defendant in their brief, for more than twenty years this property has been operated by the defendant and its predecessors, during which time there has been taken from the mine ore of the approximate value of forty million dollars. Notwithstanding such immense resources the defendant has failed, except to the limited extent heretofore indicated, to prospect this limestone or develop it.

I cannot escape the conviction that if there was reasonable expectation of finding ore by driving or cross-cutting in any direction in this limestone, the defendant, as a practical miner, at the time it ran tunnels and drifts through this intervening limestone, or since, would have cross-cut the limestone, and that it would have extended some of the many short drifts and cross-cuts now termi-

nating along the upper and lower edges of this undeveloped country.

The barren limestone lying between the upper lode and the Leadville orebody breaks the continuity of the lode, and the question of the exact identity of wall or boundary is unimportant. "In the existence of such body and to the extent of it", as stated by Judge Hallett in the Cheesman case, 116 U. S. 536, language approved by the Supreme Court of the United States, "boundaries are implied".

I am of opinion that the broad lode apexing within the mining claims of the defendant does not include within it the intervening barren limestone or the Leadville orebody.

Judgment will be entered for the plaintiff.

'MISSED HOLES' is the subject of a recent pamphlet from the U. S. Bureau of Mines. The following is a summary of measures recommended for the purpose of minimizing this danger.

1. Only unfrozen explosives should be used. Explosives should be inspected to observe that they have not deteriorated by improper storage or age.
2. As a means of making more sure the detonation of explosives, a high-grade detonator, never less than number six, should be used.
3. After a hole has been prepared to receive the charge, it should be left until it is time to blast. Then, and only then, should the hole be loaded and fired.
4. In tamping, care should be taken not to injure the fuse or electric wires. If an electric detonator is used, precaution should be taken to prevent permanent short-circuiting or open-circuiting of the firing circuit.
5. Only wooden tamping-bars should be used. Metal tamping-bars injure the fuse and legs of detonators more readily than wooden ones. Metal tamping-bars are more likely to cause premature explosions from friction or sparks.
6. In firing a series of holes electrically, the circuit should be tested with a galvanometer before connecting to the blasting-machine. Such testing should be made at a safe distance from the explosive charge.
7. Leading-wires with broken insulation should not be used.
8. A blasting-machine of adequate capacity should be used.
9. Only good-quality fuse should be used. The detonator should be attached to the fuse with a cap-crimper. The cap-crimper should be in first-class condition.
10. In the preparation of primers, the electric detonator should be imbedded in the cartridge and secured firmly in place so that it cannot become separated from the explosive. If fuse is used with a detonator, the fuse should not be imbedded in the cartridge, but secured firmly in place.
11. Misfires occur in wet holes by reason of the lack of water-proofing between the fuse and detonator. It is customary to waterproof by means of yellow soap or such patented composition as Cap-Seal or Sealakap.

The Divining Rod

By WILLIAM PRYCE

*Hooson says, that "the first inventor of the Virgula Divinatoria was hanged in Germany as a cheat and impostor:" on the other hand, Dr. Diederick Wessel Linden says, in answer to him, that "Dr. Stahl, when he was president of a chemical society in his country, published a reward of twenty-five ducats for anybody that could prove who was the inventor of the Virgula Divinatoria." It is impossible to ascertain the date or personality of this discovery, which appears to me of very little consequence to posterity: but perhaps we may not be far off from the truth, if we incline to the opinion of Georgius Agricola, in his excellent Latin treatise 'De Re Metallica', that "the application of the enchanted or divining rod to metallic matters, took its rise from magicians, and the impure fountains of enchantment." Now the ancients not only endeavoured to procure the necessities of life by a divining or enchanted rod, but also to change the form of things by the same instrument: for the magicians of Egypt, as we learn from the Hebrew writings, changed their rods into serpents; and, in Homer, Minerva turned Ulysses when old into the likeness of a young man, and again to his former appearance: Circe also changed the companions of Ulysses into beasts, and again restored them to the human shape; and Mercury, with his rod called Caduceus, gave sleep to the wakeful, and awakened those that were asleep. And thence, in all probability, arose the application of the forked rod to the discovery of hidden treasure.

Nevertheless we find no mention made of this Virgula before the eleventh century, since which it has been in frequent use. It was much talked of in France towards the end of the seventeenth century; and the corpuscular philosophy was called in to account for it. The corpuscles, it was said, that rise from the Minerals, entering the rod, determine it to bow down, in order to render it parallel to the vertical lines which the effluvia describe in their rise. In effect the Mineral particles seem to be emitted from the earth: now the Virgula being of a light porous wood, gives an easy passage to those particles, which are very fine and subtle; the effluvia then driven forwards by those that follow them, and pressed at the same time by the atmosphere incumbent on them, are forced to enter the little interstices between the fibres of the wood, and by that effort they oblige it to incline, or dip down perpendicularly, to become parallel with the little columns which those vapours form in their rise.

Now there are, first, many bodies, that in diverse cases act not, unless they be acted on! and some of them act, either solely or chiefly as they are acted on by common and unheeded agents. Secondly, there are certain subtle

bodies that are ready to insinuate themselves into the pores of any body disposed to admit their action, or by some other way effect it. Thirdly, there are bodies, which, by a mechanical change of texture, may acquire or lose a fitness to be wrought upon by such unnoticed agents, and also to diversify their operations on it, upon the force of its varying texture. All these propositions are proved from the most common, though unheeded affairs and occurrences of human life; as easily as the polarity and magnetism of an old Iron bar taken from a church window, where it has stood upright for many centuries, is proved to derive its virtue from the magnetic effluvia of the earth.

As many deny, or at least doubt, the attributed properties of the divining rod, I shall not take upon me, singly to oppose the general opinion, although I am well convinced of its absolute and improveable virtues. It does not become me to decide upon so controvertible a point; particularly, as from my natural constitution of mind and body, I am almost incapable of co-operating with its influence; and, therefore, cannot, of my own knowledge and experience, produce satisfactory proofs of its value and excellence. I shall, however, give those accurate observations on the virtues of the Virgula Divinatoria, which I have been favoured with by my worthy friend Mr. William Cookworthy, of Plymouth, a man, not less esteemed for his refined sense and unimpeachable veracity, than for his chemical abilities.

His first knowledge of the rod, he says, was from a captain Ribeira, who deserted the Spanish service in Queen Ann's reign, and became the capt. commandant in the garrison of Plymouth; in which town he satisfied several intelligent persons of the virtues of the rod by many experiments on pieces of Metal hid in the earth, and by the actual discovery of a Copper Mine near Oakhampton, which was wrought for some years. The captain made no difficulty to let people see him use the rod, but he was absolutely tenacious of the secret how to distinguish the different Metals by it, without which, the knowledge of its attraction is of little use: but by a close attention to his practice, the writer has discovered this, and made many other discoveries of its properties, which he is willing should be published, being fully persuaded of the great utility of this instrument in Mineral undertakings; and the reader may be assured, that he is fully convinced of the truth of what he communicates from abundant and very clear experience.

Captain Ribeira held, that rods cut from the nut or other fruit-bearing trees, were the only proper ones for this use; and that the virtue was confined to certain persons, and those comparatively few. Agricola says, "If the attractive power of veins does not turn the rod,

*From 'Mineralogia Cornubiensis', published in 1778. The old style and spelling have been retained.

"when in the hands of some particular metallists or others, it is owing to some singular occult quality in the holder, which impedes and restrains the attractive power; for since that power moves and turns the rod, in the same manner as the Lodestone invites and attracts Iron, it is debilitated and destroyed by the occult quality in the holder, just as garlick weakens and excludes the attractive quality of the magnet, for a magnet rubbed over with juice of garlick does not draw Iron." But this proves to be a mistake of captain Ribeira; for the virtue, as he calls it, resides in all persons, and in all rods, under the circumstances hereafter described.

The rod is attracted by all the Metals, by Coals, Bones, Limestone, and Springs of Water, with different degrees of strength in the following order: 1 Gold, 2 Copper, 3 Iron, 4 Silver, 5 Tin, 6 Lead, 7 Coals, 8 Limestone and Springs of Water. One method to determine the different attractions of the rod, is this: Stand, holding the rod, with one foot advanced; put a guinea under that foot, and a halfpenny under the other, and the rod will be drawn down; shift the pieces of money, and the rod will then be drawn towards the face or backwards to the Gold, which proves the Gold to have the stronger attraction. By trying all the subjects of the rod in the same manner, their respective attractions in point of strength will be found to correspond with the order in which I have already placed them.

The rods formerly used, were shoots of one year's growth that grew forked, as figures 1 and 2, plate 1; but it is found, that two separate shoots tied together with some vegetable substance, as packthread, will answer rather better than those which are grown forked, as their shoots being seldom of equal length or bigness they do not handle so well as the others, which may be chosen of exactly the same size. The shape of the rod thus prepared, will be between $2\frac{1}{2}$ and 3 feet long, like fig. 3, plate 1. They must be tied together at their great or root ends, the smaller being to be held in the hands. Hazle rods cut in the winter, such as are used for fishing rods, and kept till they are dry, do best; though where these are not at hand, apple-tree suckers, rods, from peach-trees, currants, or the oak, though green, will answer tolerably well.

It is very difficult to describe the manner of holding and using the rod: it ought to be held in the hands, in the position fig. 4, plate 1, the smaller ends lying flat or parallel to the horizon, and the upper part in an elevation not perpendicular to it, but 70 degrees.

The rod being properly held by those with whom it will answer, when the toe of the right foot is within the semi-diameter of the piece of Metal or other subject of the rod, it will be repelled towards the face, and continue to be so, while the foot is kept from touching or being directly over the subject; in which case, it will be sensibly and strongly attracted, and be drawn quite down. The rod should be firmly and steadily grasped; for if, when it hath begun to be attracted there be the least imaginable jerk, or opposition to its attraction, it will not move any

more, till the hands are opened and a fresh grasp taken. The stronger the grasp the livelier the rod moves, provided the grasp be steady, and of an equal strength. This observation is very necessary, as the operation of the rod in many hands is defeated purely by a jerk or counter action; and it is from thence concluded, there is no real efficacy in the rod, or that the person who hold it wants the virtue; whereas by a proper attention to this circumstance in using it, five persons in six have the virtue as it is called; that is, the nut or fruit bearing rod will answer in their hands. When the rod is drawn down, the hands must be opened, the rod raised by the middle fingers, a fresh grasp taken, and the rod held again in the direction described.

A little practice by a person in earnest about it, will soon give him the necessary adroitness in the use of this instrument: but it must be particularly observed, that as our animal spirits are necessary to this process, so a man ought to hold the rod, with the same indifference and inattention to, or reasoning about it or its effects, as he holds a fishing rod or a walking stick; for if the mind be occupied by doubts, reasoning, or any other operation that engages the animal spirits, it will divert their powers from being exerted in this process, in which their instrumentality is absolutely necessary; from hence it is, that the rod constantly answers in the hands of peasants, women, and children, who hold it simply without puzzling their minds with doubts or reasonings. Whatever may be thought of this observation, it is a very just one, and of great consequence in the practice of the rod.

All rods, in all hands, answer to springs of water.

A piece of Gold held in the hand, and touching the rod, will not only hinder its being attracted by this Metal; but, on the contrary, the rod will be repelled towards the face. It is the same in regard to Copper as well as Gold, if the latter is held in the hand.

On these properties of the rod, depends the practice of distinguishing one Metal or subject from another. There is, however, another way of distinguishing, drawn from the same principles, but much more certain and ready than the former; and that is by preparing rods, that will only operate on Gold and Copper, Iron, the white Metals, Coals, Bones, and Limestone.

Thus, if a rod is wanted for distinguishing Copper or Gold, procure filings of Iron, Lead, and Tin, some leaf Silver, Chalk in powder, Coal in powder, and rasped bones: let a hole be bored with a small gimlet in the top of the rod; then mix the least imaginable quantity of the above ingredients, and put it in the gimlet hole with a peg of the same wood with the rod, when it will only be attracted by what is left out, viz. Gold and Copper.

In preparing a rod for distinguishing the white Metals, leave out the Lead, Tin, and leaf Silver, and add Copper filings to the other ingredients; and so of every subject by which you would have the rod attracted, the respective filings, or powder, must be left out of the mixture, which is to be put into the hole, at the top of the rod. As for Coal and Bones, they may be omitted in the distinguishing rods that are used in Cornwall, for obvious reasons:

but it is necessary to put in the Chalk or Lime; for though there is no Limestone in the Mining part of the county, yet there are abundance of strata that draw the rod as Limestone; for the distinction of a dead or a live course, holds as well in regard to Limestone, as to the Metals. This, however paradoxical it may appear, is a truth easily to be proved: and it is one axiom in the science of the rod, that it makes no distinction between the living and dead parts of a course. Like the Lodestone, it only shews the course, leaving the success of the undertaking, to the fortune, skill, and management of the Miner; as the Lodestone doth that of the voyage, to the fortune, ability, and prudence of the mariner and merchant.

It is advisable for young beginners to make no experiments but about actual Lodes, where the backs of them are known by the Miners; or else nigh the sea, where a Lode being discovered, they may trace it to the cliffs, and will be sure to find it.

In the course of tracing a Lode, all the circumstances

The discovery of the Metal a Lode is naturally disposed to contain, is very easy: try it with a distinguishing rod; if it attracts it, it contains the Metal that is left out of the mixture at the top of that rod; if it draws more than one rod, the Lode is compounded of those Metals.

Copper Lodes generally draw the rod distinguishing Iron, because of the ferruginous Gossan contained in them; but Tin Lodes frequently draw none but their proper rod, unless Gal, which is a kind of Iron Ore, is intermixed.

If the Lode is alive to its top, or as it is usually phrased by the Tinnerns, To Grass; more work may be done in the way of discovery with the rod in a quarter of an hour, than by the usual methods in months, as a person has nothing to do, but to open the Lode immediately at grass, and discover its size and underlie, which may be done at a trifling expence.

The discovery of Cross-Gossans by the rod, is a property which may be usefully employed in Mining, par-

PLATE 1

of it, so far as they relate to its back, will be discovered; as its breadth at different places, its being squeezed together by hard strata, its being cut off and thrown aside from its regular course by a Cross-Gossan, &c.

In order to determine this, it will be necessary, that some one present should either cut up a turf, or place a stone at the places where the rod began, and on the other side where it ceased to be attracted.

The draughts, in plate 1, of Veins parted and proved according to the above directions, may make this sufficiently clear. The dots represent the turf or stone; and the zig zag, the line in which the operator moves in pursuing the Vein. Fig. 5, is a Lode going on east and west regularly, with the repulsion expressed by the lines north and south on each side. Fig. 6, is a Lode squeezed by a hard strata in some places almost to a string.

If the rod is well held, its motion is surprisingly quick and lively: nothing is necessary, but to keep the mind indifferent, to grasp the rod pretty strongly, and steadily; opening the hands, and raising the rod with the middle fingers, every time it is drawn down. If the rod is raised and replaced without opening the hands, it will not work.

ticularly in driving adits, as the driving an adit through a Cross-Gossan is much easier than through the country.

In seeking for water by the rod, no notice is to be taken of those single attractions of the rod which are occasioned by the commissures or crevices (called Cases of Water by the Tinnerns) between the courses or distinct runs of Killas; but a vein must be found, which answers to the rod as a Metal, and if this is sunk unto a proper depth, a good quantity of water will be discovered.

It may not be amiss to close this little essay on the Virgula Divinatoria, with some few striking instances of courses, that have been cut by means of it in Cornwall.

A quantity of grain Tin having been found in the pond at Heligan, the seat of the reverend Mr. Henry Hawkins Tremayne; and it being a question, whether this Tin might not come from some neighbouring Lode, it was discovered by the rod and sunk upon; but it proved a barren Vein for Metal in any quantity. A shaft was sunk at St. Germans, near the house of Francis Fox, to discover water; it drew the rod as Iron, and contained Mundick: another shaft was sunk between Penzance and Newlyn, according to the direction of the rod; the fast lay deep.

beneath the surface, but a Lode containing much Mundick was discovered. In a close just by St. Austle, to satisfy the curiosity of some gentlemen, Mr. Cookworthy discovered by the rod the back of a Lode that had been wrought, but not turning to advantage the undertaking had been dropped, and the ground levelled. This Lode was traced just as the Miners informed the gentlemen it ran; and the Lode appearing by the rod at a certain place to be squeezed to nothing, the Miners declared this also to be true; for at this very spot where the Lode was thus squeezed, they lost it. Being required to discover a Lode that had been tried in the cliff under St. Austle Down, he found it in the country by the rod, and traced it to the cliff. It was a large Gossan-Lode; and as the attraction was found to stop, and after passing on a foot or two to begin again, he declared this was a cleft Lode, and had what the Miners call a Horse in it, which the Miners present who had wrought in it declared to be true.

Hence it is very obvious, how useful the rod may be for discovery of Lodes, in the hands of an adept in that science; but it is remarkable, that although it inclines to all Metals in the hands of unskilful persons, and to some more quick and lively than to others, yet it has been found to dip equally to a poor Lode, and to a rich one. I know that a grain of Metal attracts the Virgula, as strongly as a pound; nor is this any disadvantage in its use in Mining: for if it discovered only rich Mines, or the richer parts of a Mine, the great prizes in the Mining Lottery would be soon drawn, and future adventurers would be discouraged from trying their fortune. But indeed, we are so plentifully stored with Tin and Copper Lodes, that some accident every week discovers to us a fresh Vein; rich Mines having been several times discovered by children playing, and digging pits in imitation of shafts, whereby profits have arisen to their parents and others; and these puerile discoveries have in sundry places borne the name of Huel-Boys to this day.

The Mexican Peon

*In the annual report of the Mexican Petroleum Company it is stated: The commencement of development gave us our first introduction to the Mexican laborer, generally known as the peon; and let me say here, in contradiction of all that has heretofore been said or may be said hereafter, that the Mexican peon is, and has been from the beginning, for us, a most satisfactory employee. He performs his task whether in the cold drizzly weather of the northern season, or under the full glare of the tropical noonday sun, with as much fortitude and more good humor than the average laborer of any class known to the American employer. Even in the latter part of April and during the first half of May of the present year, when the feeling against Americans ran high in all parts of Mexico, and especially near Tampico, and in the State of Vera Cruz, when it was deemed necessary that all Americans should withdraw from that part of Mexico (on account of the Mayo-Huerta incident at

Tampico), which they did, and left the property of the oil companies of great value scattered throughout a wide region entirely at the mercy of a people with whom it seemed probable our people might soon be at war, the natural fidelity of the Mexican employee and his friendliness toward your company which had been a friend to him, was amply demonstrated by the care with which he conserved the property left in his charge. Except for the appropriation of horses, mules, automobiles, auto-trucks, cattle, etc., as necessary war measures by both armies, no damage was done or permitted to be done to any of your company's properties. The provisions of every sort, store supplies, small hardware supplies, and many other valuable and easily removable articles were entirely unmolested. No act of vandalism was perpetrated against the oil-reservoirs, pipe-lines, pumping machinery, or refineries. The product of your continuously flowing wells was so faithfully conserved by the Mexican employees in charge that your General Manager was able to report that not more than 5000 barrels of oil were lost during the thirty days absence of your American employees from the properties.

Upon their return to the property, they were welcomed by the Mexicans in charge as returning friends, not as whilom enemies. The business of the company was resumed as before the hegira of the Americans and your company's offices recognize that the company and its stockholders owe a debt of gratitude to these particular individual employees, and that the Mexican working people are entitled to more respect and confidence than had heretofore been positively known.

A statement was also made by one of the officers connected with the United States Smelting, Refining & Mining Company: "It has been by privilege to be connected with a mining company operating in Mexico. About ten years ago we went there. We have tried to treat the Mexicans as human beings. This attitude brought out the best there was in those people and the best there was in us. For eight and a half years of revolution under those southern stars the roar of our mills has never stopped. Today 7000 men operate them, of whom 57 only are Americans (less than 1%). After Vera Cruz we insisted that all our Americans leave Mexico. The properties were left in absolute charge of Mexicans for eight months. They stole nothing; they allowed no one else to steal anything; they operated the plants successfully, and returned them to us in as good condition as when the Americans went out.

"On another occasion \$250,000 in bullion was stolen from the company. Our 6000 miners of their own notion, when they heard of this, saw to it that the bullion was returned within 24 hours, and within 48 hours it was on a Ward liner bound for Liverpool. Do you wonder that I trust them?"

DURING the first nine months of 1920 domestic production of crude oil increased 50,000,000 bbl. compared with the first nine months of 1919, while imports increased 30,000,000 bbl. This record indicates that production plus imports in 1920 will exceed 525,000,000 barrels.

*From the 'Stanford Illustrated Review', October 1920.

The Copperopolis Fire

We have received a letter from the Director of the U. S. Bureau of Mines, enclosing a letter from B. O. Pickard, district mining engineer of the Bureau, with headquarters at Berkeley, in which he demurs to our statement, in our news columns, that "the rescue-trucks arrived too late" at the scene of the fire in the mine of the Calaveras Consolidated Copper Co., at Copperopolis, California. We publish a letter from Mr. Pickard to D. J. Parker, Mine Safety Engineer of the Bureau; this letter carries conviction on the face of it, and also shows how prompt he and other members of the Bureau staff were in furnishing aid to the management at the mine. Dr. Cottrell, the Director of the Bureau, also sends us copies of warnings issued by the Bureau early last year in regard to the insufficiency of the Army mask as a protector against gases. We quote:

"The Army Gas Mask never should be used in mines, because of the uncertainty there is of the kinds and amounts of gases in the atmosphere."

Again, "The Army Gas Mask is by no means the unusual protective appliance that it is popularly believed. It does NOT afford universal protection against all gases, nor can it ever be used safely in low oxygen atmospheres."

Mr. Pickard's letter follows.

Copperopolis, California,
October 6, 1920.

My dear Mr. Parker:

You will no doubt be interested in a short preliminary report of Bureau of Mines' activities at the Calaveras Copper Mine fire. Mr. Gardner is making a complete investigation of the fire and will report at a later date.

Gardner and I were at Reno in the late P.M. of September 30, waiting for a train to go to Tonopah, Nevada, when we received a long-distance call from Hecox on Car One at Tonopah, advising the receipt of a wire from Wolfkin to me of a fire at Copperopolis. We ordered the car and crew to take the first train out of Tonopah and left on the first train going west to Sacramento; arrived at Sacramento at 3:00 A.M., where we were met by a previously engaged automobile and drove some 96 miles to Copperopolis, arriving at the mine 8:00 P.M. Friday, October 1st. We found that Cooke had broken down with the Berkeley truck eight miles out of Copperopolis and had walked to the mine, beating us there.

The underground fire was caused by a fire on surface, all of the buildings in the vicinity of the downcast air shaft were burned down and the fire was transmitted to the head frame, which burned and fell into the shaft, igniting the shaft timbers. The smoke and gases were drawn into the mine. The fire started about midnight, September 29th, and the night shift was immediately drawn out of the mine. The next forenoon the foreman seemed anxious to have a certain air valve turned on in order that the air from the compressor would clear out the gases from the main up-cast shaft, so that the pumps could be operated. A miner by the name of Lamson was

standing near by and remarked that he had a gas mask which he had used in the army, and that it was good for any kind of gas, and he would wear it and go down and turn on this valve. The foreman tried to persuade him not to go down, but Lamson was allowed to go down in the skip. As he did not return within the 15 minutes agreed upon, the foreman became alarmed, put on a dust respirator, and with another man (Kingsberry) who also put on a respirator, went down in the skip to rescue Lamson. After reaching the lower level they started down the ladder into the sump in search of Lamson, the foreman being last on the ladder. The foreman felt that he was being affected with the gas and called to Kingsberry to come up; he did not reply; immediately after the foreman heard a crash, and decided that Kingsberry had fallen down the ladder. The foreman had just enough strength in reserve to climb the ladder to the skip, and give the hoisting signal. Upon reaching the surface he was completely unconscious and was revived by rubbing and artificial respiration. The mine breathing apparatus had been burned in the fire and there had been no mine training in apparatus for a couple of years.

As soon as Mr. Gardner and I arrived we tried to ascertain the number of apparatus men available and found that there were three who might be competent in case of an emergency. Mr. Kelsey, Manager of the Argonaut Mine, was present and volunteered to do his part. We therefore organized a crew with Gardner as Captain, Cooke, Kelsey, Gregory, Chief Mining Engineer of the property, and Post, one of the Company men, who went down to the bottom of the mine to ascertain if there was any chance of the two men in the mine being alive, although no hope was held out for them. This crew went down at 4:50 P.M. October 1st, and thoroughly satisfied themselves that both men had been gassed and fallen off the ladders into the sump. Other explorations were made to start and repair pumps.

On Saturday October 2nd, at 4:30 P.M., Hecox, Donovan, and McLaughlin arrived with car apparatus and oxygen pump. At 6:20, two four-men crews went into the mine to recover the bodies. Gardner was captain of number one crew and Cooke captain of number two crew. I took charge of surface and reserve crew. McLaughlin and Hecox were on crew number one and Donovan was on crew number two, the balance of the crews' personnel were company men. Grappling hooks were used to pull the two bodies out of seven feet of water at the bottom of the 1300 foot shaft. When found Lamson had his gas mask in place and Kingsberry his respirator over his mouth. Both had fallen off the ladders and their necks were broken. At 7:33, the two bodies were brought to the surface and delivered to the coroner.

The principal purpose of this description is to call your attention to the splendid work which was done by your men. I cannot say enough for the work of Gardner, Cooke, Hecox, Donovan and McLaughlin. They proved themselves to be *real* Bureau of Mines' Rescue men, and you need never have any doubt about their actions in an emergency. Cooke drove the truck all night and broke

down about 8 miles away from the mine. He walked in to the mine, took an automobile back to the truck and brought in the apparatus and supplies, and then wanted to know what else there was for him to do. This was about 11:00 A.M. We sent him to bed to get a little sleep before going underground. His actions underground warranted us in making him captain of the second recovery crew. If he out-shined the other Bureau men, it was because they did not have the opportunities.

Gardner was always on the job "using his head", and he proved himself to be the right man in an emergency. Hecox is a natural leader of apparatus men, and demonstrated his thorough knowledge of the apparatus. Donovan and McLaughlin kept cool and worked hard and faithfully. In fact, I am very proud of the way all the men handled themselves at this fire, as it was the first fire for most of them.

My recent telegrams will give you an idea of future plans. Fighting the fire is going to be quite a problem, and I have insisted that the mine company furnish crews for the job. As the present time Hecox is training some 10 to 12 men of questionable ability, and I have suggested that the mining company hire apparatus men from the Grass Valley and other neighboring companies.

Car One will leave tomorrow for the Globe Safety Meet, leaving Hecox and Cooke to train the men, and to keep an eye on the fire. Daily trips down the main shaft to start the pumps will be necessary. This will be done with Bureau of Mines' apparatus, with Cooke and Hecox alternating as captains. I am leaving for Berkeley today, to take care of some urgent work, but will return to the property within a week.

If this information does not suffice, until Gardner turns in his final report, please wire me at Berkeley.

Very truly yours,

B. O. PICKARD.

Milling Talc

A brief description of the mill of the Uniform Fibrous Talc Co. of Talcville, New York, appears in a recent report issued by the U. S. Bureau of Mines. The ore-skip is dumped automatically in a chute leading to a picking-floor at the top of the 'rock-house'. Here waste is sorted out, thrown into a chute leading to a waste-car and trammed to the dump. The ore is shoveled into a chute leading to a 150-ton rock-bin. At the bottom of the bin large lumps are broken down with sledges and the ore is fed by shovel into a 10 by 16-in. jaw-crusher. A set of 14 by 24-in. rolls, set at $\frac{1}{2}$ in., followed by a trommel, which returns the pieces that will not pass a $\frac{1}{2}$ -in. hole, and two 8-ft. pebble-mills in series comprise the crushing equipment.

This plant is perhaps typical of the talc-plants, using intermittent dump cylinders, or short pebble-mills. The cylinders are of steel, 6 ft. in diameter by 8 ft. long, and are lined with porcelain brick. A charge consisting of one ton of talc and three tons of flint pebbles is revolved at 22½ to 23 r.p.m. for a period of four to seven hours. The finishing point is determined by visual inspection

of the product. When the grinding is completed the charging door is removed, a grating to hold back the pebbles placed over the opening, and the mill revolved until the talc all flows out into a hopper beneath. At the bottom of each hopper, which serves two mills in parallel, is a screw-conveyor which transfers the talc to an elevator, and thence to a 16-mesh revolving screen. This screen is intended to remove broken pebbles, sticks, and coarse impurities. It is estimated that 80% of the finished product is packed in 50-lb. paper sacks.

Chromiferous Iron Ore

Extensive deposits of chromiferous iron ore occur near the north coast of Cuba in Oriente and Camaguey provinces. The principal areas in which they are found are the Mayari district, 12 miles south of Nipe bay, the Moa district, about 50 miles east of Nipe bay, both in Oriente province, and the Cubitas district, 15 miles north of the Camaguey, in the Province of the same name. The deposits occur as lateritic mantles overlying serpentine and are spread over many square miles of plateaus, flat-topped ridges, and gentle mountain slopes, according to E. F. Burchard in 'Mineral Resources'. The ore is hydrous iron oxide, chiefly in the form of ferruginous yellow clay, with a top layer of spongy limonite and small hard pellets of limonite. The thickness of the deposits varies, the pellet, or 'shot', ore generally not exceeding a few feet, but the ferruginous clay is in places more than 50 ft. deep. The percentage of chromium present is generally small, but fairly constant, and serves to distinguish the ore as chromiferous as compared with the bulk of the brown iron ore mined in the southern Appalachian region of the United States. Locally, deposits contain abnormal percentages of chromium, such portions probably representing residual accumulations from broken-down bodies of chromite. Nickel is present also in the ore, but to a less extent than chromium. The Mayari district is the only one in which mining operations are carried on. Here, after careful study, successful large-scale methods were developed for mining, handling, and transporting the raw ore from the plateau down to Nipe bay, where it is subjected to treatment which not only dries the clay-like material but produces incipient fusion, or nodulization. The ore lies on a plateau about 1700 ft. above sea-level. It is mined from open-pits by drag-line excavators. The roasting and nodulizing are carried on in large rotary kilns, heated by pulverized coal and identical with those used in the manufacture of portland cement. The raw ore as mined in 1918 carried about 1.5% chromium and between 0.5 and 1% of nickel. In nodulizing the greater part of the water is driven off and the proportions of the metallic constituents are increased so that the chromium rises to about 2%. Both the chromium and nickel contents are utilized in making 'Mayari' steel, in which 1.3 to 1.5% of nickel and 0.3 to 0.5% of chromium are present. The ore is used chiefly in the Sparrows Point, Maryland, and Steelton, Pennsylvania, plants of the Bethlehem Steel Company.

The Food-Draft System of the American Relief Administration

By EDGAR RICKARD

When the American Relief Administration came to an end as a government-sustained organization and the American Relief Administration European Children's Fund was formed, we decided to limit our appeals for funds in the United States to the nationals of those countries where the after-war suffering demanded relief. We felt that to the residents of America who had emigrated here from Central and Eastern Europe must have been coming by every mail and passenger steamer such poignant stories of the mother-land's need for food that response would prove automatic.

Our first effort, therefore, was to organize among the affected nationals definite collecting agencies. We learned immediately that the appeals from Europe, on which we had counted to inspire giving, caused one other unmistakable reaction. There developed from the beginning coldness toward and even opposition to the idea of bulk-feeding. The Teuton or the Slav or the Jew in the United States was not primarily stirred by mass sympathy for his country or his race. The call was more delicately keyed than that. On his heart lay, invariably, the needs and suffering of a particular family or a group of friends and former business associates. From these persons, warmly real and near through memories of love or companionship, had come accounts of individual want.

Needless to say, the unorganized effort to relieve from this side the destitution of individuals and families in Europe met with disappointment. The kindly disposed European in the United States who went to his corner grocery store, bought haphazard articles of food, packed them unskilfully, and started them hopefully toward the interior of the Old World continent, will ever remain a tragic figure. There were thousands of them. But transportation in Europe was so chaotic, morals and the sentiment against petty thievery so lax, that the food-consignees rarely received more than notice of shipment, or perhaps an empty box from which the contents had been looted.

I am going to pass over lightly (for it is a story in itself) the period between April 21 and June 30, 1919, during which, on a vast scale, for the first time in modern history, the American Relief Administration substituted food for gold as the vehicle of foreign exchange. In those ten weeks we negotiated food-credits totalling \$8,500,000, keeping the gold of the needy governments on this side, where it could do them the most good, and accepting for the delivered food the currencies of Europe. By an order of the Federal Reserve Board, we were the exclusive agency empowered to exchange dol-

lars into the currency of the newly-created governments. The break-down of relations between bankers in this country and Central and Eastern Europe had been utter; yet we were able to rehabilitate international banking relationships through the all-powerful medium of food.

The decision to institute the plan of Food Drafts that is now in operation was reached in November of 1919. In the three months following that decision not a wheel was turned on the task itself. Day by day, week by week, the directors met soberly, formulating the 'how' of the system and seeking to guarantee against failure when the machinery should be put in motion and endeavoring to make it simple and fool-proof.

Mr. Hoover's name and ability to present a great appeal secured the services of nearly 5000 banks as sales-agencies. The co-operation of the American Bankers' Association in the handling of Food Drafts should be triple-starred in the list of American charities. The very number of the co-operating banks, however, made certain limitations manifest. It would be impossible to issue frequent revisions of instructions to such an army of representatives. The packages of food for which the drafts were to be cashed in Europe would have to be simple and unvarying in content, although five nations and two classes of consumers, Christian and Jew, had to be served. And the price of the packages would have to remain unchanged for at least a year.

That necessity for stability of price presented a problem in economics that no theoretical process could have solved. Fortunately, Mr. Hoover had superintended the transportation of two billion dollars worth of food to Europe since the beginning of the War. It was possible from the practical starting-point of that performance to arrive at a definite overhead charge to cover expenses and risks involved. The only variable item was the fluctuating cost of the commodities, which was protected by an additional margin to be returned to the Children's Fund if not required to meet unexpected increase in food prices. At the end of our three months of machinery-building, we purchased in the open market, largely on credit, \$6,000,000 worth of food, enough to protect the maximum number of Food Drafts, which at best could only be roughly approximated.

The perplexities and difficulties that beset us in those three preparatory months were almost infinite. For instance, about so unromantic a factor as the outer sacking of flour were centred vital questions. With flour, as with all our staples, we found it necessary to deal in the accepted commercial units of measurement. Something more was necessary than a dietician's word that the

food packages were made up in proper proportions of milk, flour, rice, beans, or bacon. We had to be sure that the packages could be made up readily from commercial units. In the case of the flour, it was to come in large sacks, each containing smaller 24½-lb. bags. To bring those large sacks back from Europe to America empty would have been costly. To pay for them and throw them away meant thousands of dollars loss in operations as large as we planned. To sell them for the depreciated currency of Europe would also mean loss. In the end, we had the outer sacking made of extra heavy quality, and once emptied of its smaller bags, used it as a container for the made-up Food Draft packages of food.

Another consideration that weighed heavily on every man who helped plan the Food Drafts was the tremendous impetus or setback that the quality of the food would inevitably give America's reputation in Europe. We shuddered lest some slip add to the European's fondness for the story about the Connecticut Yankee who sold wooden nutmegs. Incalculable harm had just been done the American manufacturer in the minds of the Germans, for example, by the flooding of Germany with bacon containing an excessive amount of preservative. This meat, treated according to Great Britain's orders for supplies when the English feared that submarine warfare might isolate them completely, was intended to remain edible at least three years. Consequently, it was barely edible when packed. The wide sale of this meat, marked 'American bacon', in Germany after the War, almost defeated the Food Draft plan in that country.

With the determination that every Food Draft package should be an international evidence of America's good faith and an advertisement of America's modern methods, we put our own inspectors into even the proudest packing houses in the country. And every form of foodstuff purchased had to undergo the same sort of uncompromising inspection. In our allowance for cost, we made provision for buying, in every instance, the highest quality of food obtainable on the market, and for inspecting even the Grade A product.

In order to protect ourselves against sharp changes in the food-market, it was necessary to put the Food Drafts on sale at a price that would leave a contingency margin. This we did, with the advertised provision that any unused portion of this margin, which would be called profit in a commercial enterprise, would be used to feed the needy children of the countries into which the Food Drafts went. In spite of the contingency allowance, the difference between the food-value purchased by the individual under our plan and what he can buy in any other way in the world, has become proverbial. We early had to institute the most stringent precautions to avoid the purchase of the Food Drafts for speculative purposes.

The putting of the plan into operation, its endorsement by the United States and European governments and scores of organizations, the actual sale of 180,000 drafts, and the delivery in Europe of \$5,000,000 worth of food are virtually current history. It was no little

satisfaction that the excess margin accruing under the plan up to August 1, 1920, a total of \$605,194 was turned over to the governments of Austria, Hungary, Czecho-Slovakia, Poland, and Germany, for use by their branches of the European Children's Fund.

I believe that this winter will see a new figure set for Food Draft sales. Certainly the need is great. In the meantime, it can be said for all the men who planned the venture that no one in the world is more surprised than they at the scarcity of weak points that have come to light in the eye of eight months operation. The urge of the appalling suffering that the plan has helped and is helping to alleviate must have caused some Power to endow our scheming and working with success beyond our mental deserts. There was no chart in the sea of international finance and economics by which we could steer. We are more than happy, in plain language, to have 'got somewhere'.

CHROMIUM does not occur native but appears in about a dozen minerals in the form of oxides, chromates, sulphates, and silicates. Chromite, an oxide of chromium and iron, is practically the only commercial source of chromium. It is composed when pure of 68% of chromic oxide and 32% of ferrous oxide. In nature, however, some of the chromium in chromite is replaced by aluminum or iron. Much of the rich imported ore contains 50% or more of chromic oxide, but the average American ore contains only about 40%. Chromite is a common constituent of basic igneous rocks, especially of peridotite, which is composed largely or wholly of olivine or pyroxene. As rocks composed of olivine and pyroxene readily alter to serpentine and the chromite in them remains unchanged, the most common occurrence of chromite is in crystalline grains widely distributed in serpentine. Chromite is used for making alloys, chemical compounds, and refractory materials. The most important alloy is with iron in ferro-chromium used in making chrome steel, which is remarkable for its hardness in resisting wear and penetration. Its principal application is in armor plates and shells for piercing them, as well as in special parts of aeroplanes, automobiles, and engines, and in stellite for high-speed cutting tools and parts of other machinery. Chrome-steel is extremely hard, tough, and dense. It possesses great tensile strength and is superior to any other metal known for the wearing parts of mills used in crushing. Chrome-steel, though hard, bends well cold if the operation is slow enough. It can be welded to iron and rolled out and finds use in sheet metal and rod metal, especially as material for burglar-proof safes, wire, magnet-steel, cutlery, bridge-steel, tires, axles, springs, stamp-mill shoes and dies, crusher-jaws, knuckles for car-couplings, lathe tools, drills, and chisels. The steel for shoes and dies for stamp-mills if compressed hot in a hydraulic forging press removes internal porosity and renders the steel of equal density and wear-resistance throughout.

OF 170 of State Public Service Commissions only six are members of a National Engineering Society.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

RICH LEAD ORE FOUND IN THE ARIADNE MINE AT SAN JUAN.

CENTRAL CITY.—A new body of rich copper-silver-gold ore is reported opened in the Evergreen mine at Apex. A large tonnage of milling ore is broken and awaits improvement in copper prices. The mill in the meantime is not operating. Development work continues at the Saco De Oro property at Apex where the Barrick tunnel vein has recently been opened by the shaft.

DURANGO.—Operations will be continued this winter on the Ten Broeck, Lewis mountain, by the Lewis Mining & Milling Co. as a result of the recent discovery of a new five-foot orebody assaying from \$12 to \$25 per ton in gold and silver. The property is situated seven miles from La Plata city. Operations at the Esmeralda on the south fork of the Lightner and at the Jumbo mine near Mayday have been discontinued for the winter. Heavy snow storms have begun already.

GEORGETOWN.—The Sunburst company, financed by Eastern capital will continue operations on its Democrat Mountain property this winter. A large compressor has been ordered and development on Astor-Stewart mines will be pushed as soon as the plant is in operation. The Georgetown Tunnel Co. has shut-down its mill and is driving the big 'bore' to its objective under the old producing mines of Democrat mountain.

IDAHO SPRINGS.—The Walder group adjoining the Reynolds at Alice has been taken over by the Roosevelt company. There are eight claims in the Walder group that with little development have produced ore of good grade. Additional equipment including another battery of stamps is being added to the mill and a compressor is being installed. The Shafter mine is again to be operated. A force is now engaged cleaning up and re-timbering old workings. The Shafter has a record for production of high-grade gold ore worth several millions. A bond and lease on the Gum Tree, presumed to have the extension of the Freeland vein, has been secured by Lee Gibson and associates of Idaho Springs. The mine has excellent prospects. Lead-silver-gold ore assaying as high as 186 oz. silver, 0.5 oz. gold, and 4% lead has been opened by local leasing pool on the Ship Ahoy. The Silver Age leases are producing and shipping a good grade of ore. Chicago capital has become interested in the Specie Payment and preparations are being made to start development.

LEADVILLE.—The proposed 'Home' mining company

is reported to be eliciting the support of citizens and a meeting is scheduled to name an executive committee to select a desirable property for operation. Increased production will result from the increased operating force secured for the L. & M. lease on the A. Y. and Minnie. The Bartell lease on this property is mining and shipping silver-lead ore at the rate of about a car per week. The ore nets close to \$1000 per car. Chrysolite lessees have opened up a rich silver-lead vein averaging 40% lead and 11 to 16 oz. silver and are shipping steadily. A local company has been organized to operate the Gold Leaf adjoining the Emma and Mabel mine. Machinery is being installed preparatory to sinking a deep shaft.

SILVERTON.—A 14-in. streak of lead-copper ore assaying better than \$100 per ton has been opened up at the 650-ft. level of the Ariadne mine, in San Juan district, and with a week's development the ore has widened to two feet. The same vein is producing for the Ariadne Mining Co. in three levels above and the shaft is also in ore. Development will continue and ore will be stored during the winter. The construction of an aerial tram is planned for next spring. Work is continuing on the Eastern Star, where development in the tunnel is reported to be encouraging.

MICHIGAN

SHIPMENTS OF COPPER DURING OCTOBER.—DEVELOPMENTS AT ARCADIAN CONSOLIDATED.

HOUGHTON.—October copper shipments by water totaled 8,322,000 lb. This is an increase of 1,648,000 lb. over September, but it is far below the normal for October, practically the last month of the year that shipping is without hazards. November tonnages usually are small. The total shipment down the lakes this year is 53,156,000 lb., compared with 49,596,000 in 1919. Heavy rail shipments in the late spring months bring the 1920 total considerably over that of last year and with a number of small mines closed, the end of 1920 should leave the producers with smaller stocks on hand than at the close of 1919.

Coal shipments this year have not fallen so far below the 1919 figures that any of the larger mines are in danger of a shortage. The combined cargoes shipped since May total 498,454 tons. A year ago, 621,686 tons of soft coal was shipped into the district, so in view of the general shortage during the summer the Lake Superior region has fared well. With the mines on a basis

varying from 50 to 60% of normal, these stocks of fuel should tide them over until the opening of navigation.

October 'rock' production figures reveal an improvement for Osceola, which reports 7000 tons for the month. This is an increase of 1325 over September. The Kearsarge branch also shows a betterment, with a tonnage of 37,700, against 35,550 in the preceding month. Ahmeek, on the other hand, dropped slightly from September, reporting 69,300 tons, compared with 73,050. On an estimated yield of 22.5 lb. to the ton, Ahmeek's refined copper output for October is 1,559,000 lb., or 50,000 below the total for September. Superior made no shipments during the month and no tonnage is reported by LaSalle.

Copper Range Consolidated this week started using a mechanical shovel that promises well. It is operated by one man, whose average is 24 tons of rock per day, whereas one shoveler removes but 10 or 12 tons of rock in an 8-hour shift. The Copper Range also is devising a shovel with a belt-conveyor for the purpose of sorting underground. Various mines in the district are experimenting with mechanical shovels and stope-scraper, with some success. Owing to differences in size of openings, however, it is necessary for each mine to work out its own individual problems. A device that will work satisfactorily in one mine will not work in another and the difficulties peculiar to each property will result in a variety of devices.

Arcadian Consolidated, at a depth of 700 ft. in its New Baltic shaft, is in the vein and the showing is described as good. The characteristics are identical with those on the 400, 500, and 600-ft. levels and from appearances the mineralization is as good at the present depth as nearer surface. Instead of cutting a station at 700 ft. it is planned to continue to the 750-ft. point before a level is put in and there will be no intervening level between that and the 900-ft. station. While it has not been definitely announced whether operations will continue through the winter, in all probability there will be no delay in pushing the shaft down to the 900-ft. level. The identity of the New Baltic vein, as regards correlating it with lodes opened on other mines, has not been established and it may be that this particular orebody never was opened elsewhere for the reason that it is far to the east of Kearsarge amygdaloid. It is for this reason that the Arcadian developments are of interest to the mines to the north for it may be that the same lode will be found all along the range into Keweenaw. The fact that the New Baltic lode was not discovered by the early explorers is explained by the overburden of 60 ft. which was penetrated before the vein was tapped.

Hancock Consolidated has completed the construction of a concrete wall on its 53rd level and operations in the property have temporarily ceased. The wall, built to take care of surface-water flowing through drifts and in addition to protect Hancock's new openings, will prevent the water from flooding Quincy's openings in No. 7 shaft. Hancock does not plan to resume operations until the market is stabilized and the demand for copper is such that full-time operations are warranted. The territory

east of the main Pewabic lode, chiefly on the 49th and 53rd levels, has been thoroughly developed. With present high costs for fuel, wages, and mining supplies, Hancock's management concluded to conserve resources rather than dip into the treasury to pay development expenses. Among the new openings that are regarded as highly favorable are those on No. 12 amygdaloid, which was opened in a cross-cut from the 44th level. No. 3 lode also disclosed fair ground. When Hancock decides to resume, the mine will be in fair condition to produce at once, save for minor repairs in the milling plant at Point Mills in which it holds an interest.

NEVADA

EXTENSION GRANTED ON INGALLS OPTION.

TULE CANYON.—W. A. Ingalls and W. B. Mercer, owners of the Ingalls mine, have extended six months the time for the second payment to be made by the Silver Hills, holder of the option, and have agreed to grant a further extension of six months if the Silver Hills requests it. It is understood that work is to be resumed immediately under this agreement, the entire effort of the company in the mine to be devoted to exploring the 200-ft. level. The mill, which the company started to dismantle, will be left standing and will be used for retreating the tailing made before cyanidation was started. Mercer says it is his opinion that the shaft passed far out of the vein between the 100 and 200-ft. levels and that the recent work has been done 70 ft. from the main ore-channel. It is understood there will be a complete change of management and Mercer is confident the work now planned will result in ore being found on the 200-ft. or bottom level. The Silver Hills took over the Ingalls on February 12 of this year for \$125,000, the payments to extend over two years. The option was signed after W. J. Loring had inspected the workings. The adjoining Jaegers group of six claims was optioned for \$20,000 at the same time. Ingalls has been owner on part owner of the mine for 30 years and what is reported to have been some of the richest silver-lead ore sent from the State was shipped over the Nevada & California railroad to San Francisco 20 to 25 years ago. The production to date is estimated at \$225,000 gross, made almost entirely by lessees.

RENO.—Work is to be resumed in the Standard Metals a copper-silver-lead mine north of Reno, on November 1 according to A. L. Chappel, manager. No attempt will be made to operate the 60-ton concentration and flotation plant until spring and the winter will be devoted to further development of the mine on and below the third, or 215-ft., level, which is 500 ft. from the surface on the dip of the vein. There has been exposed on the upper level an ore-shoots 150 ft. long and 10 to 50 ft. wide. This ore can be treated in the mill at a good profit, according to reports. The mill concentrates on Wilfley tables 60-mesh material, which is re-ground to 100-mesh and then treated in an 8-ft. K & K flotation machine. In test-runs made last summer with a concentration ratio of 11:1 by the combined processes the tables gave a \$75 product and the

flotation machine a \$200 product. The Standard Metals is three miles west of the Black Panther.

PIOCHE.—In a report to stockholders the directors of the Black Metal, operating a copper-silver-lead mine in the Jackrabbit district, 14 miles from Pioche, give the production as 17,602 tons of flux ore of a net value of \$111,074. The report says: "Considering the large amount of ore shipped it would seem that a reasonable profit should have been realized instead of a loss. To those familiar with conditions in connection with the operation of a mine during the last year little explanation is necessary." Referring to the mining of a low-grade orebody under present conditions, the report continues: "Railroad tie-ups, car shortages, inefficient labor, and inability to get sufficient men to operate the mine at more than half capacity are the principal items that wiped out the profit of your company." Machinery cost \$18,000 and the report, which says a financial statement is being prepared, indicates that there was a heavy expense for other equipment. An assessment of two cents per share has been levied.

It is stated that the Virginia Louise Mining Co. will increase its output immediately; a contract having been entered into with the American Smelting & Refining Co. for 50 tons of fluxing ore per day, in addition to the contract for 75 tons per day entered into some time ago with the United States Smelting Co. The shipments being made at present come from the 2nd, 3rd, and 5th level stopes. There are three principal beds of iron manganese in the mine. The upper, or Davidson, averages from 40 to 55 ft. in thickness and lies at the bottom of the limestone, where it comes in contact with a bed of shale about 100 ft. thick. Below this shale is the 'big bed', from 80 to 100 ft. thick. Under this is a paring of limestone, 15 to 20 ft. thick, below which is a 20-ft. bed of manganese. The Virginia Louise also has had a considerable amount of high-grade silver-lead ore, mixed with the fluxing ore, in the lower workings of the mine. During the week ending November 6, the Prince Consolidated shipped 1250 tons; Virginia Louise, 510; Bristol Silver, 100; Consolidated Nevada Utah, 175; and Ida-May property, 45; making a total of 2080 tons. Michael Kinsella and Owen Walker, who recently secured a lease on the Great Eastern mine, owned by the Bristol Silver Mines Co., have found ore averaging 12% copper and 50 oz. silver. A number of leases have recently been given by the Bristol company, and shipments are increasing in spite of the high freight-rates.

ELY.—The orebody recently opened on the 700-ft. level of the Nevada Consolidated proved to be 150 ft. long, 50 ft. wide, and it extends 60 ft. above the level, with an

average copper content of 7%, according to C. B. Lakenan, general manager. "The body is at a contact of lime and porphyry, and a 10-ft. width next to the porphyry assays 12 to 18%. The orebody is a secondary enrichment of the pyritic mass on the limestone side of the contact, brought about by the precipitation of copper from migrating copper sulphate solutions," Mr. Lakenan says. He adds that the deposit "indicates other similar orebodies might be found around the lime-porphyry contact", and drilling has been started from the surface in search for such ores. A drill also will be used on the 700-ft. level to explore the downward extension of the orebody recently found.

VIRGINIA CITY.—The Northern Light Comstock, incorporated last month to develop a claim adjoining the Concordia, will work through the 300-ft. level of the Con-

CAMP AT STONEWALL, NEVADA

cordia shaft, according to an announcement made after a meeting of the incorporators, R. L. Colburn, N. R. Harris, T. J. Pearce, A. D. Cunningham, and L. F. Grimstad, all of San Francisco.

UTAH

MINERS ARE MORE PLentiful IN PARK CITY AND EUREKA.—SILVER KING COALITION STARTS COMMISSARY FOR EMPLOYEES.

SALT LAKE CITY.—Carl A. Allen, State Inspector of Mines, has submitted to the Industrial Commission of Utah statistics covering the employees in metalliferous mines, mills, and smelters of this State during the past three years. During 1919, 4599 men were employed for an average of 325 days at underground and surface mines, as compared with 6901 in 1918 and 7937 in 1917. The concentrating mills employed an average of 1382 men during 1919, as compared with 1942 in 1918 and 4103 in 1917. The smelters employed an average of 1832 men in 1919, as against 3173 in 1918 and 2658 in 1917.

Auxiliary works employed an average of 709 men in 1919, 1885 in 1918, and 2811 in 1917. This makes the total number of men employed in the mining and treatment of ores 8522 during 1919, 13,901 during 1918, and 16,509 during 1917.

ALTA.—Considerable anxiety is being caused the officials of the Alta-Superior Mining Co. as to the whereabouts of Frank Tyler and Herbert Waterworth, who were doing work under contract at the property of the company, five miles from here. N. A. Nelson, secretary of the company, was at the property on October 6, and the men asked for a month's supply of provisions, which were sent to them on October 11. As no word had been received for a month, a party of three made the trip to the mine on skis on November 10. No sign of the men was found, and not more than a two weeks supply of the food had been used. About 575 ft. from the mouth of the tunnel and about 50 ft. from the face, the searching party encountered a big cave of talc from the roof. It is feared that the men were entombed, or that they may have been caught in a snowslide, which for years has been the terror of this camp during the winter season. The snow at the Alta-Superior is about eight feet deep. Work was immediately started clearing the tunnel to ascertain if the men were entrapped by the cave.

PARK CITY.—The labor situation shows a marked improvement over the conditions obtaining during the past summer, and the larger mines are now gradually getting their forces up to normal, as well as increasing efficiency. During the week ending November 6, a total of 1843 tons was shipped, of which the Daly-West and Judge contributed 692; Silver King Coalition, 601; Ontario, 490; and Naildriver, 60. At the Keystone the management is directing its energies toward the development of ore and is making no attempts to stope. At present, two drifts and three raises are being run. In the face of K-K 3 tunnel, which is all in ore, assays indicate returns of 35% lead with 15 oz. silver. Sufficient supplies have been taken to the property to permit development throughout the winter. The Silver King Coalition Mines Co. is the latest mining company in Utah to supply groceries, fuel, and clothing to its employees at cost plus a small percentage for handling the goods. The company has purchased a coal-yard and other buildings necessary to carry out this plan. The company now has a larger payroll than it has had for the past six months. As fast as men are obtainable, they are being put on development work. On the 1100-ft. level the 'quartz' drift is being run to the south-west and the Blood drift to the north-east. Both drifts are coming through a lime formation, close to the contact.

BINGHAM.—A promising find was made recently at the Silver Shield property, according to F. L. Block, mining engineer of Salt Lake City. In a stope about 200 ft. from the present orebodies, 18 in. of ore averaging 30% lead, 10% iron, and 7 oz. silver has been uncovered. Mr. Block is of the opinion that the lime bed in which this ore occurs is the Jordan lime strata, which is one of the productive beds in the United States mine, adjoining the Silver Shield. During the early part of the year,

mining men familiar with the district were of the opinion that the work being done by the Silver Shield company was too far into the mountain, whereupon efforts were directed toward the locality where the recent find was made.

EUREKA.—All of the mines in this district report an improvement in the labor situation, which is reflected in the heavier output during the week ending November 6, when 166 cars of ore were shipped. Of this number, the Chief Consolidated shipped 43; Tintic Standard, 45; Mammoth, 17; Dragon, 14; Eagle & Blue Bell, 13; Iron Blossom, 7; Iron King, 6; Grand Central, 4; Centennial-Eureka, 4; Gemini, 4; Victoria, 4; Swansea, 3; Eureka-Hill, 1; and Bullion Beck, 1. Shaft No. 2 at the Chief Consolidated property has passed the 1750-ft. level; the total footage sunk during October being 132. It is planned to sink the shaft to a depth of 1900 ft. For some time past, the shaft has been in a solid shale formation and the concreting of the last few hundred feet will be deferred until the sinking is finished, which it is expected will be accomplished by the end of the year.

As a result of the drop in price of copper and the expiration of its smelting contract, the Mammoth Mining Co. has suspended ore shipments, according to Earl McIntyre, manager. The mine force is being kept together and is engaged in development work. Shipments from the dump are being made, and Mr. McIntyre hopes that a new contract can be negotiated which will permit of shipments from the mine.

WISCONSIN

REVIEW FOR OCTOBER.

Depression in the zinc-mining and smelting industry, further accentuated during the month of October, was mainly responsible for a curtailed production at mines in the Wisconsin field, and a relative drop in the amount of high-grade blende marketed. The shutting-down of the American Metal Co.'s smelters in Arkansas narrowed the outlet for zinc ore; the buyer representing this concern locally withdrew at a time when the buying was the most constricted ever known to the field. The Mineral Point Zinc Co. had the field to itself almost entirely during the month, the only other smelter to be represented being the Illinois Zinc Co., at Peru, Illinois. However, the Mineral Point Zinc Co. did not turn the situation to its advantage, as offerings on zinc ore remained steady most of the month.

Lead ore received bad treatment at the hands of buyers, declines being rapid and sharp until the price dropped to \$65 per ton, at which figure lead-ore producers no longer cared to market and shipments for the month were the lightest reported at any time during the year. The beginning of the decline found sellers expectant and much ore held in bin was carried along in the belief that a recovery in price would be a matter of a short period at most. These declines have been steady and at present there are about 2000 tons of lead ore in the field unmarketed. Producers of carbonate-zinc ore withdrew from the market some time ago.

The manufacture of sulphuric acid, which has become important in the Wisconsin field, has been carried on successfully at the National Separators at Cuba City, the production amounting to 40 tons per day. This product was for a time marketed in Chicago and Milwaukee, but recently it is claimed that the demand has not been so good and that a more determined effort to market became imperative. Shipments continue at the rate of one 25-ton tank-car daily with the acid department of the Mineral Point Zinc Co. shipping three or four such cars weekly.

Deliveries of zinc ore and lead ore from mines to refineries were made for October by districts as here shown.

District	Zinc, lb.	Lead, lb.
Benton	8,954,000	140,000
Livingston	6,736,000	160,000
Cuba City	2,108,000	60,000
Galena	1,828,000
Day Siding	1,666,000
Platteville	948,000
Shullsburg	736,000
Hazel Green	586,000
Highland	150,000
Total	23,712,000	360,000

Shipments of high-grade blende from refiners to smelters were made by the following concerns:

District	Lb.
Mineral Point Zinc Co.	5,204,000
National Zinc Separators.	4,080,000
Wisconsin Zinc Roasters	1,260,000
Linden Zinc Separators	478,000
Block-House Mining Co.	468,000
Total	11,490,000

The gross recovery of milled ore for the month aggregated 11,566 tons, net to smelters, 5745; carbonate-zinc ore 45. The high-grade blende went to the Prime Western Smelters, 416 tons; Illinois Zinc Co., 726; American Metal Co., 498; Mineral Point Zinc Co., 4105 tons.

BRITISH COLUMBIA

NICKEL PLATE MINE SUSPENDS OPERATIONS.—REPORTS FROM THE PREMIER PROPERTY.

HEDLEY.—The Hedley Gold Mining Co. has closed the Nickel Plate mine, throwing 150 men out of employment. So far as the men are concerned, they hardly are deserving of sympathy, as, notwithstanding that they have been warned time and time again that it would be impossible to continue operations and pay increased wages, they have been insistent in their demands for increases. J. P. Jones, the general manager of the mine, has made the following announcement: "During the World War we continued operations at Hedley as we felt it to be our duty not only to British Columbia and to the Allies, as gold was needed, but also a moral obligation to the town of Hedley. After the Armistice we continued to operate, thinking all costs would come down and allow us to make a fair profit. We have been disappointed in this conclusion, and find that we cannot earn reasonable divi-

dends under existing circumstances and maintain our ore-reserve. We have accordingly recommended to the board of directors that the property be closed down until conditions change. This will probably mean a shut-down of a year. The mine, mill, and other plant should be in good condition to start-up when conditions justify it." There has been a persistent rumor that the Consolidated M. & S. Co. had been negotiating for the purchase of the mine, but it is difficult to see what its object would be, unless it proposes to start the manufacture of germicides and needs the arsenic. Latterly the Nickel Plate has been producing \$20,000 worth of arsenic yearly. There is another rumor that the Hedley company proposed to combine with a strong United States smelting company in the exploration of the Bradshaw and Nick-of-Time

INTERIOR OF A ZINC-MILL IN THE PLATTEVILLE DISTRICT, WISCONSIN

claims, north of Hedley. These claims are said to contain ore similar to the Nickel Plate, but with a higher arsenic content; the gold running about the same.

TRAIL.—During the last ten days of October, 12,125 tons of ore and concentrate was received at the smelter, the Consolidated company's mines contributing 11,230 tons. The other shippers were: Bluebell, Riondel, 185 tons; Emerald, Salmo, 38; Granby, Grand Forks, 91; Josie, Rossland, 228; Monarch, Field, 33; North Star, Kimberley, 159; Paradise, Athalmer, 35; Ruth, Ainsworth, 63; Skyline, Ainsworth, 55; and Waterloo, Edgewood, 8. The total ore received for the ten months ended October 31 was 296,662 tons. This is only about 30,000 tons less than was received during the whole of last year, so, if this rate of shipping keeps up until the end of the year, the total quantity of ore handled at the smelter should be considerably more than last year. Most of the ore during the present year has come from the Sullivan mine, consequently more zinc ore has been treated than any other kind.

STEWART.—H. A. Guess, of the American Smelting & Refining Co., spent the first few days of the month at the Premier mine, and he stated that he was entirely satisfied with the development of the mine, which fully has come up to expectations. An attempt has been made to start shipping before the snow covered the whole of the

road, but it was found to be unsatisfactory. One consignment of 50 tons went to Tacoma. It is expected that the snow will enable regular shipping to commence soon after the middle of November, and an attempt will be made to get at least 3000 tons of high-grade to the Tacoma smelter this winter. This will have a gold and silver content worth between \$800,000 and \$1,000,000. Two snow-tractors are now on their way to Stewart, and will be used in shipping ore this winter. These are said to have been thoroughly tested; the one tried last winter was an experiment and a failure. The new water-power plant is nearly finished, and will be in operation early in December. The concentrating and cyanide-plant should be finished early in the spring. It was expected that the plant would have been finished by the end of the year, but the severe rains that fell during last summer completely ruined the road from Stewart to the mine, and made the hauling of heavy machinery impossible. Much of the machinery for the plant is still on the wharf at Stewart. Bert F. Smith, of Hazelton, has been appointed assistant to Dale L. Pitt, manager of the mine.

W. A. Meloche, managing engineer for the Algonian Development Co., states that ore will be shipped this winter from the Spider mine, and that if the development planned shows a tonnage equal to three times what is in sight, a mill will be working on the property by next July.

VANCOUVER.—A clean-up of 50 gold bars valued at more than half a million dollars was made at the Dominion Government assay office and shipped to the mint at Ottawa. The staff at the mint report that the season, so far as gold mining is concerned, has been very unsatisfactory, both as regards British Columbia and the Yukon. The water-shortage interfered with placer operations at both places, and the closing of the Rossland mines, which essentially are gold mines, for a large part of the year has reduced the gold output of British Columbia markedly. The closing of the Nickel Plate mine will be a great blow to the lode-gold mining of the Province.

ANYOX.—The Hidden Creek mine of the Granby Consolidated Mining & Smelting Co. has 11,000,000 tons of ore designated as No. 1, containing 2.4% copper, and 14,000,000 tons designated as No. 2, containing about 1.25% copper, according to a recently published report. Direct smelting is said to be applicable to the No. 1 ore, but the No. 2 will become available after concentration.

NELSON.—The Ottawa mine is rapidly being put in shape for operation and shipment of ore. Machinery, including a tube-mill, is on the ground, and the cable for the tram is at the upper terminal, which has been finished. The latter will be about 2000 ft. long. L. H. Biggar, the mine manager, is satisfied with the progress made.

ONTARIO

MINERS MORE PLentiful AT COBALT.

COBALT.—The labor supply at Cobalt is becoming more plentiful and efficiency has increased considerably during the few weeks. Operators believe it will be possible to

reduce the per-ounce cost of producing silver and thereby make up for the reduced income caused by the lower quotations for the metal. The McKinley-Darragh has closed down its oil-flotation plant for the winter. The equipment will again be employed following the spring break-up. Ore in the Keeley silver mine is estimated to contain 400,000 oz. of silver. This has been placed in sight as a result of less than one year's development work. Other properties in the South Lorrain area, in the vicinity of the Keeley, are now attracting attention.

The Ontario Bureau of Mines has issued a detailed report on the geology and the output of silver from the Gowganda district. The report declares the rocks in Gowganda to resemble in a general way those at Cobalt. Production reached the highest point in 1917, amounting to 1,064,639 oz. The second highest record was in 1919 when 722,564 oz. was produced. In the ten years from 1910 to 1919, both years inclusive, the district produced 5,430,152 oz. In view of operations having continued steadily throughout the current year, the production to the end of 1920 is estimated as likely to reach 6,200,000 oz. Cobalt mine-operators believe the price of silver is going up. A large quantity of bullion is being held in store at the mines. The opening of the new year is expected to find quotations around \$1 per ounce, or equal to the price being paid American producers under the terms of the Pittman Act.

SUDBURY.—It is officially announced that the output of the International Nickel Co. will be reduced from 4000 to 3000 tons of nickel matte per month, bringing production down to the pre-war basis. One furnace is being shut-down and the working force reduced by about 250 men. The cause assigned is business depression in the United States.

PORCUPINE.—The development of a large orebody on the McIntyre below the 1000-ft. level, paralleling the No. 5 vein, is regarded as of importance not only to the McIntyre but to the Hollinger Consolidated, as the deposit is ascertained to be a continuation of vein No. 84 of the Hollinger. So far as this deposit has been opened in the latter mine it is estimated to contain ore to the value of \$6,282,620, this amount being chiefly above the 800-ft. level, and its continuance to the depth now reached on the McIntyre will greatly increase the ore-reserves of the Hollinger. Up to the present the Hollinger has developed 38 veins, and has 39 veins, which have not yet been opened for mining, outcropping on the surface.

The ore in sight on the Porcupine Vipond-North Thompson, including development work down to the 600-ft. level, is estimated at approximately 130,000 tons valued at \$1,250,000. The company is planning to sink to the 900 or 1000-ft. level and open up main haulage levels, and to remodel and extend the 100-ton mill.

KIRKLAND LAKE.—The Moffatt-Hall which has 12 claims on Crystal Lake, Lebel township, has put up buildings and done preliminary work in stripping and test-pitting. Some of the orebodies have been proved to be large and to yield good assays. Funds have been raised for the resumption of operations.

THE MINING SUMMARY

ARIZONA

Ajo.—A ten-ton hoist has been installed at the Copper Ridge mine preparatory to sinking the present 30-ft. shaft to the 100-ft. level. From this point cross-cuts are to be run to several known veins from which 40% ore has been taken near the surface. Several shipments of high-grade ore have been made in the past. This property was formerly known as the Ajo Cornelia and adjoins the Ajo Consolidated claims of the New Cornelia on the east and south. Nearly all the stock of the company is held locally.

Kingman.—A larger force of men is being put to work at the Antler mine of the Newby Mines Co. A carload of ore is being shipped to the railroad at Yucca, two more cars being on the dump. It is reported that there is a considerable tonnage of 8% copper ore now developed which when dressed will yield a 20% concentrate. The lease was obtained on the property a year ago. The mine produced a large tonnage of ore years ago.—It is reported that a strike of high-grade silver ore has been made at the O'Fallon mine west of Cerbat. The ore is said to be 30 in. wide and assays 250 oz. per ton in silver. The mine is owned by the Jones brothers and is under option to Percy Allwyn, who is developing on the old levels. The mine has produced some high-grade silver-lead ore in the past.—The Big Four Metals Co. is making preparations for extensive development at the mine in the Wallapai mountains. A hoist and compressor have been ordered and the old road is to be repaired. The ore carries gold, silver, lead, and vanadium; the last running high. J. S. Garrison is in charge of the property.

Kayser brothers and Jackman, who are operating the Neptune mine, have driven a drift along the vein opening splendid ore. A carload of the ore is on the dump and is said to average 200 oz. per ton in silver. Grading and the cement foundations for the mill at the C. O. D. mine have been completed. The machinery for the mill is expected any day. The drift on the 400-ft. level has opened ore, specimens of which are very rich. Each foot of development work opens more ore. It is said that there is a year's supply of mill-ore now developed. C. P. Sherman is in charge of development work.

CALIFORNIA

Shasta County.—On the petition of the United States Smelting, Refining & Mining Co., the suit brought against it by the Shasta Copper Exploration Co. has been transferred by the Superior Court to the United States courts. Both companies are claiming the same mining ground in the neighborhood of Kennett.—In the Little Nellie mine near Iron Mountain a body of copper ore has been found in the new drift run from the bottom of the 500-ft. winze sunk recently, thus proving the contention of the company that what has always been a gold mine would prove to be a copper mine when developed in the direction of the Iron Mountain mine.—E. K. Kirkland of Weaverville and Sim Mack of San Francisco have taken a two-year option on the Washington mine near French Gulch and have set a crew of eight men at work.

Nevada County.—An aeroplane has made a test of the feasibility of serving a circuit of mines in this region with gut supplies and mail. The plane made a circuit of ap-

proximately 60 miles over the mining region, landing just 51 minutes from the time of starting. The route included Morning Star, Iowa Hill, Birds' Flat, Little York, You Bet, Red Dog, Nevada City, and the Grass Valley district. Most of these places are off the railroad and on poor roads and it is estimated that it would require eight hours to reach them by automobile.

San Benito County.—The New Idria Quicksilver Mining Co. has announced that its mine will be closed down temporarily, owing to the stagnation of the metal market.

COLORADO

Denver.—The twenty-third annual convention of the American Mining Congress opened in this city on November 15, with delegates in attendance from all sections of the United States. Questions of importance to the mining industry were considered under nine general divisions, as follows:

1. Present-day relations between operator and employee; increased efficiency in production; wages, hours, working conditions, and contracts.
2. Tariffs pertaining to mine products and the uniformity of national and state mining laws.
3. The feasibility of holding a national conference on the standardization of mining machinery, and labor and life-saving devices.
4. The existing excess-profits tax law declared to be unfair to the mining industry.
5. The problem of the decline of the nation's gold production, and means of preventing further depletion of the nation's monetary reserve.
6. War-minerals.
7. Relief of claimants for compensation who, under existing technicalities of the law, are often denied relief.
8. The petroleum industry and the development of the vast oil-shale deposits in Colorado and other States.
9. National and local problems of the coal-mining industry.

IDAHO

Coeur d'Alene.—Activity is increasing in the silver belt lying along Big creek. The Yankee Boy mine, a steady contributor of high-grade ore, has shipped another carload said to assay \$100 per ton. The Big Creek company is running dump-ore through the mill, producing a high-grade silver concentrate. The development of the mine is proceeding. The Sterling Silver Mountain company has purchased 10 claims adjoining the property on Big creek. The new claims are on the line of the vein being developed.—The Western is engaged in assessment work. The First National will cross-cut the vein in the lower tunnel. The Big Hill & Silverdale company is driving a cross-cut that has attained the 700-ft. point.—High-grade tungsten ore has been found in the property of the Kennon Mining Co. in the North Fork district. The ore was assayed to determine its gold content and the presence of tungsten was discovered. The tungsten ore is eight inches wide in a vein five feet wide. The ore contains \$5 to \$6 in gold.—The best ore yet found in the Ajax mine was cut recently, according to A. C. Bixby, manager. It is a full face of good milling ore in the east drift. The company some time ago sunk a shaft

200 ft. from the Moonlight vein and sunk a winze 120 ft. on the vein. From the bottom of the winze it drifted 150 ft. Most of this distance the tunnel followed a vein of good milling-ore about a foot wide. As this vein did not change, the work was turned to an east drift where the full face of ore was found.—An assay certificate received recently by the Nabob Consolidated mine shows that the last carload of lead concentrate shipped contained 54% lead, 7% zinc, and 21 oz. of silver per ton. This is the highest recovery made in the mill. The car contained 40 tons and was produced since new equipment was installed.

Talache.—The Armstead Mines Co., whose property is on Lake Pend Oreille, is engaged in the development of a body of milling ore, according to H. H. Armstead, president. The principal content is silver.

MONTANA

Butte.—The Davis-Daly Copper Co. is producing approximately 1,000,000 lb. of copper per month. The company has just finished installing a new hoist and erecting new and modern buildings. This construction is being paid for from earnings, and costs at present are averaging between 13 and 14c. per pound. Shipping its ore to the East Butte smelter, which settles on receipts of shipment, Davis-Daly is not tying up cash in unsold copper. There is a discussion now going on between Anaconda and Davis-Daly relative to the apex rights to one of the latter's main veins. The former company intimated that it had ownership through apex rights to this particular vein and is now endeavoring to prove its allegations. Davis-Daly is awaiting the results of its big neighbor's findings.—The zinc-producing mines are curtailing production. Butte & Superior has reduced its output by 30%, and at Senator Clark's Elm Orlu mine a similar reduction has been made. A number of the Anaconda company's zinc mines have discontinued production entirely pending improvement in the market for zinc.

MANITOBA

The Pas.—The syndicate headed by W. B. Thompson, of New York, which holds an option on the Flin Flon copper deposit, has completed an arrangement with the Manitoba government under which a survey will be made for a railway to the mine. The Government did not feel inclined to undertake the cost involved until it had assurance that the syndicate would exercise its option. Not being able to give such assurance the syndicate proposed that the Government should proceed with the survey on its undertaking to pay the cost, including an estimate of the cost of constructing the railway, in case it failed to take up the option and develop the mine. This proposition was accepted, the cost being fixed at \$15,000. The survey work will be done by the engineering department of the Canadian National Railways, and a report with reference to the cost of construction will be made for the Provincial government to present to the next session of the Manitoba legislature. The syndicate has spent \$200,000 on the Flin Flon property and if the option is exercised must pay \$1,000,000 on March 1.

Obituary

Chester A. Thomas, formerly manager for the American Smelters Securities Co., and a mining engineer of wide reputation, died at Dawson, Alaska, on November 11. He was in Alaska, re-visiting the scene of his early engineering career at the time of his death. For years he was in charge of the Guggenheim interests in Alaska, and later in California and Arizona. He left San Francisco last August. Shortly after his arrival at Dawson he suffered a breakdown in health. He is survived by a widow and three children, all of whom are residents of Berkeley.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Edwin E. Chase is at Butte on professional work.

O. Hondrum has left Cananea, Mexico, and is at Jerome, Arizona.

George D. Blood has moved from Salt Lake City to San Francisco.

Bond Coleman has moved from Mound City, Kansas, to Pachuca, Mexico.

T. A. Rickard is in Denver attending the meeting of the American Mining Congress.

Walter Fitch Jr., mining contractor of Eureka, Utah, has returned from a trip to Juneau, Alaska.

Duncan MacVichie, president of the Western Utah Copper Co. at Gold Hill, Utah, is at Los Angeles.

E. W. Engelmann, consulting research engineer for the Jackling porphyry interests, is in New York.

A. H. Lawrence has just returned to Santiago after spending several months in the wilds of Bolivia and Peru.

Henry N. Thomson has accepted the chair of metallurgy in the University of British Columbia at Vancouver.

T. M. Hamilton arrived on the 'Huron' on November 4, from Buenos Aires, and will reside at Lewistown, Montana.

Arthur H. Carpenter has become assistant professor of metallurgy at the Armour Institute of Technology, Chicago.

Frederick Lyon, formerly vice-president of the U. S. Smelting Co., has been visiting the company's properties in Utah.

August Grunert, mining engineer of Butte, has been making an examination of the Tungsten Comet mine, near Pioche, Nevada.

H. Foster Bain, **Marshall D. Draper**, and **T. K. Li**, having finished their work in Yunnan, China, are returning to the United States.

George E. Drewitt has concluded his mining report for the financial house of Jose I. Lazama, Havana, Cuba, and will sail for Spain and England.

G. A. Overstrom is visiting the properties of the Seoul Mining Co., in Japan and Korea. He will not return to this country until the first of the year.

M. W. von Bernewitz has re-joined **W. H. Weed** in compiling the 'Mines Handbook', whose office is now at Tuckahoe, 16 miles north of New York city.

Walter Hovey Hill has been in the East for the past month, and is now at Stanley, Idaho, as consulting engineer to the United Metals & Power Corporation.

George Crerar has joined the working force of the El Fuerte Mining & Smelting Co., at Choix, Sinaloa, Mexico, and will have charge of the installation and operation of the copper blast-furnace.

Arthur W. Burgren, assistant superintendent of the Dolores mine at Mathuala, Mexico, is at Knights Ferry, California, convalescing from a recent illness. He expects to return to Mexico in a month.

Jerome A. Hilbert has resigned his position as superintendent of the Blue Ledge mine, at Copper, California, to become superintendent of the Cia. Metalurgica Mexicana, at Sierro Mojada, Coahuila, Mexico.

Herbert Hoover, **Theodore Hoover**, **James M. Hyde**, **David McClure**, and **H. W. Turner** will, after December 1, have offices in the new Balfour building. Herbert Hoover will retain an office in the Mills building as well.

Albert L. Waters, having just finished a two years engagement, is continuing as mining engineer and general superintendent for all the mining interests of Charles E. Richardson & Co. in the province of Kwangtung, south China, with headquarters at Swatow.

THE METAL MARKET

METAL PRICES

San Francisco, November 16

Aluminum-dust, cents per pound.....	65
Antimony, cents per pound.....	9.50
Copper, electrolytic, cents per pound.....	16.50-17.00
Lead, pig, cents per pound.....	7.25-8.25
Platinum, pure, per ounce.....	\$85
Platinum, 10% iridium, per ounce.....	\$125
Quicksilver, per flask of 75 lb.....	\$55
Spelter, cents per pound.....	9.50
Zinc-dust, cents per pound.....	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

November 15.—Copper is quiet and steadier. Lead is dull and lower. Zinc is inactive but easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

FOREIGN EXCHANGE

Premium on New York exchange is a virtual tariff on European imports. Each decline of 5% in sterling, for example, adds just that much to cost of our commodities. How badly Europe is in need of our products can be seen from the high premium the various countries are obliged to pay for American funds.

Recent weakness in exchange carried many to new low records. The following table shows the discount in New York of the principal exchanges, compared with low records previous to the present downward movement which started on offerings of grain and cotton bills:

Exchange	Par	'Low' previous to present movement	Discount, %	'Low' Nov. 8	Discount, %
Sterling	4.86	3.18	34.7	3.33 1/4	31.5
France	0.193	0.0579	70.0	0.0574	70.3
Libre	0.193	0.0373	81.7	0.0338	82.5
Mark	0.238	0.0101	95.8	0.0109	95.3
Guilders	0.402	0.3125	22.0	0.2940	26.9
Swiss	0.193	0.1928	15.3	0.1507	21.9
Sweden	0.268	0.1630	39.2	0.1848	31.0
Norway	0.168	0.1380	48.1	0.1302	51.4
Denmark	0.268	0.1375	48.1	0.1303	51.4
Pesetas	0.193	0.1470	23.6	0.1270	34.2

England pays one-third premium. France pays more than three times normal, Italy more than five times normal, and Germany more than 20 times. Certain bankers maintain that an adverse exchange-rate is a blessing in disguise. They point out that it discourages imports and encourages increased home production and exports. One prominent international banker says that, in his opinion, England could fix her rate well above \$4 if she would withdraw her support from the Continentals. He states, however, that there are certain advantages of a low rate at present and it is doubtful whether she really desires a higher exchange-rate.

RAILROAD OPERATION

The statement that six months of private railroad operation since March 1 cost the taxpayers approximately \$650,000,000 while 26 months of government operation cost only \$900,000,000 is characterized as unfair.

The Labor Board's wage-award increased by over \$600,000,000 the annual payroll, and approximately one-third of this advance was covered in the period between May 1 and September 1. In the six months period ending September 1, \$175,000,000 more was spent for maintenance of way and \$220,000,000 more for maintenance of equipment than in the corresponding period of the preceding year. These increased expenditures for wages and upkeep practically offset the entire \$650,000,000 government deficit for the first six months.

As a result of operating economies and efficiency efforts inaugurated since cessation of government control the roads have raised car mileage from 22.3 to 27.4 miles per day. Averaging loading per car was 29.8 tons on September 1, an increase in six months of 1.5 tons. Result of this increased movement and heavier loading has been to add the equivalent of 600,000 cars to freight service.

MONEY AND EXCHANGE

Eastern Metal Market

New York, November 10.

All the markets are quiet and buying power is small. They are all fairly steady as to prices except tin, which has declined more than the others.

The copper market is steadier and quotations are firmer at the recent low levels.

Tin has declined and there is almost no buying.

The lead market is a little easier but fairly steady and buying is very light.

The zinc market is almost lifeless and prices have eased slightly.

Antimony is dull and a little lower.

IRON AND STEEL

Current steel-trade activities have to do mainly with cancellations of orders, further restriction of output of pig-iron and steel, and continued efforts by manufacturing consumers to reduce inventories and contract obligations before the end of the year. There are few new orders and more and more reminders of the aftermaths of some well-remembered booms.

It develops that here and there an independent producer would accept some business at the Steel Corporation prices, but in the main diminishing demand is met by cutting down output and by such an orderly retreat from the higher price-levels as will protect unfilled orders now on the books. As has been the case for some weeks, Steel Corporation mills are running nearer to capacity than the average independent plant, the percentage being about 80 for the former and 50 to 60 for the latter. The corporation's statement of unfilled orders on October 31 (not published at this writing) is expected to show a falling off of several hundred thousand tons.

Companies whose business is largely with motor-car makers have slackened further. The turning point in the latter industry is not in sight, little response being made to the first price-reductions.

COPPER

This market is steady but quiet. It is felt by some that the bottom has been reached. At least the continued decline has stopped at the 15c. level and rested there for over a week. On small lots for prompt delivery there has been a little shading of this price but it has been largely where cash needs were imperative. Buying by domestic consumers has improved but the betterment is slight. One bright spot is the continued sale to foreign buyers. This is not of large proportions, but it is steady at prices above domestic levels. We quote the market for both electrolytic and Lake copper at 15c., New York, for delivery the rest of this year and at 15.25c. for the first quarter.

TIN

This market has grown weaker and prices have again declined to levels obtaining about three weeks ago. Two factors are largely responsible: The speculative London market and the fall in exchange, though large supplies and poor buying power are also powerful influences. The London market in the last two days has had severe declines from the high points reached in the speculation following the favorable turn in the British coal strike and has nearly approached the level following the actual strike. Yesterday spot standard tin was quoted at £245 15s. and future standard at £251 15s. with spot Straits at £248, all recessions of £11 to £22 per ton below the values on November 1. The New York market is also lower with 37c., New York, quoted for spot Straits yesterday. The market here is stagnant with consumers uninterested and with dealers neither buying for the long pull nor trading in the other way. There has been

no activity on the New York Metal Exchange the past week. In the general market there were offerings last Friday of spot Straits at 37.50c., New York, and of tin for November-December shipment at 40c. with a little business. London is reported to have tried to buy but when its bids arrived sellers at those levels had withdrawn. They were really few at the best. Arrivals thus far this month have been 2150 tons with 3640 tons reported afloat. Imports to November 1 this year have been 44,923 tons against 25,896 tons to November 1, 1919. Of this year's imports 32,340 tons was from the Straits Settlements.

LEAD

There have been few developments in the last week. Quotations are nearly nominal, so little is the actual business transacted. The outside market has declined a little further to 6.75c., New York, or 6.50c., St. Louis, for early delivery at which levels, slightly above or below, some small business has been done. One dealer described the market as a catch-as-catch-can affair. Imports of 1000 tons of lead from France arrived on Monday but all sold in advance. The imported metal has practically vanished as a market price-factor. Late on Monday the leading interest reduced its quotation $\frac{1}{2}$ c. per pound to 6.75c., St. Louis, or 7c., New York, for early delivery, another adjustment to meet the outside market.

ZINC

Conditions are but slightly changed. Prime Western for early delivery is a little lower at 6.80c., St. Louis, or 7.25c., New York, but demand is of small proportions. The only buying consists of hand-to-mouth needs by galvanizers. Brass-makers are not active as to operations and their needs are less. Producers are not forcing sales and are still disinclined to sell for future delivery. Stocks are declining as well as production and the technical position of the market is regarded as sounder. Large operators are reported to have reduced the price of galvanized sheets one cent per pound which is something of a surprise.

ANTIMONY

There is almost no activity and prices have declined slightly. Wholesale lots for early delivery are held at 6.25c., New York, duty paid. Jobbing lots are $\frac{1}{2}$ c. to $\frac{1}{4}$ c. per pound higher.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted by the leading producers at 32.90c. f.o.b. producer's plant in wholesale lots for early delivery, while from other sources it is quoted at 28 to 29c. per pound, New York.

ORES

Tungsten: Quotations are nominal at \$4.50 for Chinese ore and \$5 per unit for Bolivian in regular concentrate and there is almost no business.

Ferro-tungsten is unchanged from the quotations reported last week.

Molybdenum: There is no demand and quotations are nominal at 75c. per lb. of MoS₃ in regular concentrate.

Manganese: There have been no developments and quotations are nominally unchanged at 45 to 50c. per unit, seaboard. Imports have been very heavy to October 1, this year, or at the rate of 47,001 tons per month which has been exceeded only once—in 1918 at 52,490 tons per month.

Manganese-Iron Alloys: There is no demand for ferro-manganese or spiegeleisen and quotations are unchanged. The former is quoted at \$155, basis seaboard, for re-sale, and \$170 for domestic and foreign alloy from producers, the latter at \$75, furnace, with re-sale material available at substantial concessions.

MARCY ROLLER MILL

THE Marcy Roller Mill represents a high development in grinding machinery and in this respect is in the class with the Marcy Ball Mill.

The open end feature, through which the conditions within the mill may be observed while running, brings about low cost of operation.

Rods or rollers can be used in a tube mill but for the best results, *bent and broken rods must be removed.*

High efficiency in the roller mill is obtained by the low pulp line as in the Marcy Ball Mill

Thirty six large size Marcy Roller Mills are now being manufactured for one of the large mining corporations of the Southwest.

We will be glad to advise on your crushing problems

The Mine & Smelter Supply Company

DENVER

SALT LAKE CITY

EL PASO

NEW YORK OFFICE: 42 Broadway

T. A. RICKARD, . . . Editor

ELSEWHERE in this issue we publish an article describing the custom plant for manufacturing zinc oxide, recently built by the Utah Zinc Company at Murray, Utah. The important item of freight frequently defines the grade of ore that can be stoped profitably when it must be shipped away from the mine for treatment. There are in Nevada and Utah a number of small mines that have been unable to profit from considerable deposits of medium-grade lead-free zinc ore because of the distance to the nearest market. The terms on which the Utah Zinc Company will purchase ore may be worth investigation by owners of prospective zinc properties in neighboring States.

PRODUCERS of copper and zinc are not alone in their difficulties. The International Nickel Company has curtailed its production of nickel matte from 4000 to 3000 tons per month, owing, it is said, to "general business depression throughout the United States". The slump in automobile manufacturing is doubtless an important factor. An antidote for this disagreeable announcement may be found in the decision of the company to construct a \$3,000,000 plant for the rolling of monel metal at Huntington, West Virginia. Monel metal combines structural strength with the quality of resisting corrosion and is being used in an increasingly large number of industries. Some of our friends in Canada are disappointed that the plant could not have been built as an adjunct to the refinery at Port Colborne, but the availability of cheap fuel and consequent additional profit seem to have had greater weight with the directors of the Nickel company than an international boundary—which, on the whole, is desirable.

THE zinc-mining industry in the West is comatose. On November 1 the Interstate Callahan company in the Coeur d'Alene suspended production, officially assigning as the reason the labor troubles at the plants of the Grasselli Chemical Company, to which the Interstate Callahan ships its zinc concentrate. While the Grasselli company did request that shipments be suspended, we suspect that the operating deficit of \$28,372 for the third quarter was the controlling factor in determining the action. At Butte the Anaconda company has shut-down three of its zinc mines, the Alice, West Gray Rock, and Poulin, and the Butte & Superior company stopped pro-

duction entirely at the middle of the month. Butte & Superior recorded an operating loss of \$147,000 during the second, and \$102,000 during the third quarter of 1919. The average selling-price used in estimating income for the two periods was 7.64 and 7.53 cents respectively, but the price during October and November was considerably lower, so that the deficit for the last quarter threatened to be still greater. The heavy character of the ground in the Butte & Superior workings makes an unusual amount of current mine-repair necessary, so that the 'shut-down' expense will be approximately \$75,000 per month. However, the ore-reserves are not being depleted when production is suspended. Operating costs, including charges for depreciation, but making no allowance for taxes and depletion, were \$11.45 per ton for the third quarter, as against \$11.52 for the quarter ended June 30. This last figure is the maximum in the history of the company, even exceeding the period of low labor-efficiency during the War. We hope that it will be but a short time before the present adverse margin between production-costs and selling-prices is converted into a favorable one, and our friends in Montana and Idaho are able to resume mining.

MR. HOOVER, on November 18, was chosen to be the first president of the newly created American Engineering Council. This is to be the governing body of the Federated American Engineering Societies organized, as declared in the constitution, for the purpose of "furthering the public welfare wherever technical knowledge and engineering experience are involved, and to consider and act upon matters of common concern to the engineering and allied technical professions". Engineers have long been handicapped by the absence of any organization by means of which their individual ideas might be co-ordinated; there has been no machinery for concerted action. The new federation is to be composed not of individual engineers but of a large number of engineering societies, both local and national. These member societies do not resign any of their present functions, nor is their individual identity submerged in any degree; they simply agree to co-operate with the hope that united effort will be effective where unorganized energy would be wasted. Some 70 organizations representing 100,000 engineers have already signified their intention of affiliating with the Federation. It is urged

that every society of engineers in the country become a member, in order that the weight of its influence may be behind Mr. Hoover and the other representatives on the Council. The beginning is auspicious.

MR. W. J. LORING has been elected president of the American Mining Congress in succession to Mr. Bulkeley Wells, as announced at the banquet of the Congress at Denver on November 18. The news of Mr. Loring's election to this honorable and important position will give keen pleasure to his friends in California and to the mining profession in many parts of the world. As Governor Boyle of Nevada said, the selection of Mr. Loring as president indicates a recognition by the directors of the Congress of the larger responsibilities and interests growing out of the present period of reconstruction in which the international phases of industry and commerce are insistently engaging the attention of thoughtful men. Mr. Loring has been engaged professionally in many lands and under divers flags, notably the flag that has flown closest beside our own in the Great War; therefore he brings to the activities of the Mining Congress an amplitude of economic vision, in regard to mining particularly, such as should prove of great value to its further capacity for public service. He follows a gentleman who endeared himself to the members of the Congress by his personal charm and public spirit; to Mr. Wells the Congress owes a debt that it is glad to acknowledge. He remains as a director and will support his successor in office. We wish Mr. Loring every success in his new departure.

A GOOD example has been set by the Esperanza, Ltd., an English company operating at El Oro, Mexico. We refer to the prompt publication of telegraphic news from the mine. This apparently decadent mining enterprise came suddenly into prominence by reason of the cutting of a rich vein on the fifth level; it opened out handsomely, the assays of the ore running into hundreds of dollars per ton in gold and silver; then almost as suddenly the orebody petered out in both drifts, north and south. The share-quotations, of course, reflected these vicissitudes of fortune and opportunities were offered for some tall gambling. Now, in former days, and with other companies, it was not uncommon for such news to be kept secret pending an opportunity for the directors and their friends to buy or sell stock in accordance with the good or bad news; indeed, one of the supposed compensations for serving as a director was this access to inside information, that is, instead of considering themselves as trustees for the shareholders such directors regarded themselves as privileged speculators. Some deals that were pitiful ethically but handsome financially were perpetrated in this way. Shareholders had reason to suspect the chicane, and protested feebly, but it was difficult to prove and the scandal would blow over. No better opportunity for ways that are dark has been offered than by the Esperanza affair and we note with pleasure that it was respectfully declined. In other words, the

directors and the secretary did what was right, and in a manner that left nothing to be desired.

CO-OPERATION is the solution of our industrial development, according to Mr. Hoover. The projects of the future are too big and too complicated to be carried out successfully by individual effort. Problems of finance, politics, and engineering are involved. There are ahead of us enterprises so large that private capitalists cannot finance them without guarantees from the Government; so extensive that Federal as well as State governments must co-operate; and so complex technically as to tax the resourcefulness of engineers of every kind. An example is the plan to construct an immense system for electric-power distribution to include eleven of the North Atlantic States. With this end in view engineers of the United States Geological Survey are making a survey of the territory to allocate and appraise the waste incident to the present production and distribution and to devise means for its correction. It is proposed to construct a huge trunk transmission-line which will be fed from large steam-power plants situated at the coal mines, supplemented by the central stations now operating in New York, Philadelphia, Baltimore, Washington, Boston, Providence, and the other large cities, and sundry hydro-electric plants, which it is interesting to note will supply but 15% of the total. In the area of 60,000 square miles comprehended in the district there is required now approximately 17,000,000 horse-power, of which 7,000,000 is for railroads. By supplying a large part of this power from a main distributing system \$300,000,000 per year is to be saved, according to the estimates so far made. Half of this economy will be in the saving of 30,000,000 tons of coal; half in the lesser cost of operation and maintenance of electrical machinery as against the large number of small steam-units that now supply the power. The average load-factor in the area being surveyed is 15%; it is believed that this can be increased to 50%, and that the consumption of coal can be reduced to half. The cost of the project has not been calculated, but if \$300,000,000 is to be saved it is apparent that a capital investment of tremendous size would be warranted.

Concerning Shift-Bosses

The superintendent of a mine employing about 600 miners recently remarked that, if he could find twelve men whom he knew to be as good shift-bosses as the twelve he already had, he would put them to work at once with confidence that he could thereby reduce the cost of mining at least 10%. He added that any member of the staff, including himself, could be replaced more readily than some of the shift-bosses. Doubtless he exaggerated, for the sake of emphasis; nevertheless the remark expresses a fact that is not always appreciated. The shift-boss serves as a buffer between those who direct the work and those whose manual labor must accomplish it. A good boss must be loyal to the company, but at the same time he must not lose sight of the fact that the men under him expect him to look out for their welfare.

He must be a diplomat if he is to avoid trouble. The category of the successful shift-boss's qualifications includes many characteristics. In the first place, he must know exactly how the work should be done. While an exceptionally good miner frequently fails as a shift-boss, a man who has no more than average ability as a miner rarely fills the part. He cannot retain the respect of his men unless they believe that his knowledge and judgment of the best way to do a thing are, as a rule, better than their own. This, obviously, applies to any kind of supervision, but in underground operations it is especially important, first, because there are no rule-of-thumb methods that will fit all conditions, and second, because in a large mine it is impossible to consult with the foreman or superintendent whenever unusual situations arise. It is here that the young college graduate is likely to find the greatest difficulty. Unless he has had sufficient experience in 'handling' ground as a miner or timber-man he is at a serious disadvantage, for the men soon discover his shortcomings. The shift-boss must set a personal example to his men; unless he is diligent, energetic, and careful, unless he co-operates with others, the men under him are likely to be similarly deficient. Nothing is more detrimental than a lack of co-operation between the miners as well as between the shift-bosses themselves, whose activities are, in varying degree, dependent on each other. The tendency too frequently is to consider one's individual record, without regard to the welfare of the mine as a whole. The most important qualification is doubtless that intuitive quality, the ability to handle men; this requires sound judgment, tact, a habit of square-dealing, the ability to discipline strictly yet fairly, a large stock of common-sense, and the personality of a leader among men. A boss's judgment must enable him to measure his men and deal with them according to their individual peculiarities. The day of the boss who rules by virtue of his prowess with a pick-handle has passed; the time when the Western miner wants to be addressed as 'Mister' has not yet arrived. Methods that may secure good results from one man may simply antagonize another. It is for the shift-boss to fit the treatment to the individual; to do this he must have tact. Tact also is essential for maintaining discipline; likewise fairness. Few men will complain of strict rules if they are uniformly enforced. Miners, like the rest of us, are indignant if they see another man favored with special privileges; it is also true that they resent any action on the part of the shift-boss that imposes unnecessary hardship on a fellow miner. A strict but impartial boss who has no favorites and pays-off no grudges, but is absolutely 'on the square', succeeds where the lenient one, who lets his personal feelings influence his treatment of the men, fails utterly. The measure of a shift-boss's success is, of course, the amount of profitable work that the men under him accomplish in a year, rather than in a day, or in a month. Personality is an important factor. Some men can give a peremptory order, a casual direction, a suggestion, or a request—and the man who is told to do the work does it as a matter of course. Others, who

try to boss, antagonize a man by their very attitude; the miner resents their instructions no matter how they are given. Many of these qualifications are needed in any man in a position of authority, but to a varying degree; they are perhaps more necessary in a shift-boss underground because of the conditions amid which the work is done, that is to say, in the dark and in places where constant supervision is impracticable. Moreover, the average miner is 'temperamental'; he is continually complaining, sometimes in earnest, more often from habit; and he is always on the point of "calling it deep enough". It is little wonder that shift-bosses who really measure up to their job are hard to find, and that the superintendent whom we quoted at the start uses fewer bosses than he would like to have because he cannot find men properly qualified. Apparently young college-men are not in demand as shift-bosses. As one manager says, "unless a graduate is prepared to put in several years of hard work as a miner he had better get his underground education while serving as a surveyor, sampler, or engineer. If he is observant and intelligent he can learn enough about the manual operations of mining to become a superintendent or executive, but the chances are not in favor of his becoming a good shift-boss." This may seem strange; but it is the deliberate opinion of more than one successful executive. What then is the best material for a shift-boss? Apparently the best are the men who have had enough elementary schooling to be able to read intelligently, write readily, and figure fairly well, and who started to mine as soon as they were big enough to do a day's work. If the college-boy is to become the shift-boss of the future he must go through a similar, though shorter, course of practical instruction. Meanwhile we feel warranted in saying, with confidence, that a great deal of bad work is done in mines and much ore is overlooked on account of the attempt to run a mine with too few shift-bosses.

The Brass Check

A friend has sent us a copy of Mr. Upton Sinclair's book, the title of which will be cryptic to most people, for it signifies the symbol of prostitution. The sub-title is 'A Study of American Journalism'. It is a book of 450 pages and is crowded with first-hand information. We found it intensely interesting and recommend our readers to get a copy of it from the author, whose address is Pasadena, California. The price of a single paper-covered copy is 60 cents post-paid. Like most of Mr. Sinclair's writings—like his 'The Jungle', for example—this book cannot be included in what is called 'polite' literature; there is no mincing of words or softening of rough places with euphemisms; he hits out roughly and viciously. The book is marked by bad taste in its first part, in which he tells about his personal affairs, his conjugal troubles, and other matters that most people would consider intimate; he is crudely egotistic and egoistic; but the general effect is to give authenticity to this revelation of newspaper corruption and to heighten the disgust, if not dismay, evoked by the recital. In the latter half of the book he

discusses his subject less violently and apart from his own vendetta, so that he becomes more convincing. As our criticism will have indicated, the book is not pleasant reading, any more than his exposure of the Chicago stockyards, but it is written with marked literary skill and it is one that every serious man ought to read, because it bares a condition of affairs that undoubtedly undermines the very roots of democratic institutions in the United States.

Mr. Sinclair presents a mass of evidence to prove that our newspapers and magazines are unreliable, subservient, and corrupt. When he touches upon matters about which we happen to know, we find him correct, so that we infer that in the main his testimony is trustworthy. We make this reservation however: that he singles out the "capitalistic" press for special attack, whereas we have no reason to believe that the radical press as a whole is any better as regards perversion of news and the subordination of editorial opinion, and the frankly anarchist press, with which Mr. Sinclair has evident sympathy, is open to the charge of vicious disloyalty to our institutions. Early in his career he fell foul of the editors of the metropolitan press, because he attacked the 'trusts'; and he found himself balked by the brick wall of fortified capitalism. That made him bitter. Then he discovered that the papers cared less for honest information than for sensational claptrap. When he attacked the Beef Trust in 'The Jungle' and in newspaper articles, his so-called muck-raking placed him under the ban; everything he did was misrepresented in the newspapers; his socialistic ventures were smothered with organized ridicule. He became angry. He went on the warpath. Hence this book. It is an *ex parte* statement, of course, but he speaks from the inside, and with detailed knowledge of his subject. He quotes the personal experiences of sundry friends, as well as his own. All this is done not in vague terms, but with names and dates; it is specific. He shows how fictitious telegrams are concocted and published; how lies are printed, and how they remain uncorrected when protest is made; how editors play the lackey to rich patrons; how headlines are made to misrepresent the news below them; how the yellow papers lie and cheat; how wholesale falsehoods are foisted on the public either for cheap sensationalism or for a private interest. For example, a newspaper publishes its own views and labels it a "special dispatch" from Washington. Another publishes telegrams, day after day, signed by imaginary correspondents in London, Paris, or Berlin, all of them simply a rehash of items appearing in the London papers. The whole system of news-giving and current comment is in the hands of predatory exploiters, who either own the papers themselves or own the editors or get what they want by means of subsidies and bribery. By aid of the press a small group of clever and unscrupulous men exercises an industrial and political power that stultifies our whole system of republican government and renders ridiculous the democratic ideal. Most of us know, by personal observation, how Senator La Follette was killed politically by an organized campaign of silence concern-

ing him in the newspapers, and how that was clinched by publishing one big lie. We hold no brief for him nor for Mr. Sinclair; we quote them as part of the record in the case against the press. Next come the news agencies, which poison the news at its source. Nine hundred daily papers receive and print the news dispatches of the Associated Press. Think what a power that represents; it means that a sensational telegram from a reporter is printed about fifteen million times and read by thirty million people. The reporter may be honest and intelligent; he may be controlled or bought by somebody. The Associated Press may use the reporter of a local paper as its correspondent, and he may be in the employ of one side in a big controversy; it may publish a lie sent by an agent in the interest of an individual or a corporation. Such lies or mis-statements appear in thousands of newspapers; and correction is futile, even if attempted. Great wrongs are perpetrated and bitter feelings are generated by the controlled press, which confines its argument not to the editorial columns but uses the news columns for propaganda and either fails to print the news, or tampers with it, or invents lies. All of these things are done, and one of the results is to cause social unrest, to provoke hatred against organized wealth, to incite a destructive type of radicalism. Obviously the big news agencies should be treated as public utilities and be subjected to discipline instead of being run as a piece of private property. The tampering with a news dispatch, the publication of a concocted telegram, or the placing of a lying headline should be rendered punishable as fraud. Every paper should be licensed, and the license should be withdrawn when proof is furnished that the newspaper is guilty of gross misdemeanors; in short, the public and the nation should not be at the mercy of a predatory press or be debauched daily by yellow journalism. We in San Francisco know what that means: two in the morning and two in the evening. Mr. Sinclair pays his compliments to our local press, but he expresses admiration for Mr. Fremont Older, formerly of the 'Bulletin', whose recent cynical avowal of his own performances suggests the low state of press morality in this city. Mr. Sinclair has a good deal to say about the press of Denver, with which also we are well acquainted; it can be said of Denver and of San Francisco that if a community gets the kind of press it deserves then it is about time for the people of Denver and San Francisco to become severely introspective and ask themselves what they have done to deserve it. Here we may add that we take no stock in the suggestion that American papers are exceptionally bad; the same kind of prostitution degrades the press of Europe, and no city has such a numerous and varied gutter press as London. However, that is no consolation. They have Northcliffe and we have Hearst; let the contrast suffice. Both are a menace to democratic ideals. Indeed, the healthful development of our institutions is incompatible with controlled news agencies and a prostituted press. We recommend our readers to get a copy of Mr. Sinclair's book, examine the evidence, and arrive at their own opinion on the subject.

The Business Outlook

By Charles T. Hutchinson

Deflation, nearly two years overdue, is under way. The artificial abnormal boom that affected every branch of industry on account of the War is subsiding fast, and now "normalcy" is upon us. Industry is experiencing the pangs incident to a gorged stomach full of rich food, and the purging process is painful but necessary, while the chances for a better and bigger constructive development of Nature's resources are brighter than ever.

War's demands threw all of the considerations under which business is ordinarily conducted into the discard. Price or cost was relegated into a secondary place. Delivery became the prime consideration. Time was the essence, and as everything had to be produced at abnormal speed in spite of the reduced productive capacity consequent to the withdrawal of millions of labor-units for military service, an artificial shortage of labor ensued that brought the cost up to an unheard of figure.

The result was the 'silk shirt' period. The three-dollar-a-day man, finding himself in the possession of ten dollars, fifteen dollars, and even twenty dollars for one day's time, rather than one day's labor, went on a joy-ride. So did his boss. They bought lavishly of totally unaccustomed things. The vendor of fancy clothing, the purveyor of pleasure cars, the real-estate man, and the rest of the crowd experienced a boom the like of which they will probably never experience again. Our Uncle Sam himself took part in the fray, and devised a fearful and wonderful system of taxation designed to skim most of the cream off the War profits, in order that the inevitable headache of the morning after might be assuaged by some money in the treasury with which to pay the bill.

Now that the fog of battle is clearing, stock-taking is under way. Prices, securities, and all sorts of commodities are passing slowly and tortuously through the clothes-wringer of readjustment, and the water is slowly trickling out. It hurts. There is no doubt about that, but, as the conscientious mother said to her fractious child when administering corporal punishment with vigor and the aid of a slipper, "Johnny, this is altogether for your own good."

It is not surprising that the labor unions are restive at the realization that the old easy-going slackness in factory discipline is about over. Bad habits are easy to acquire, but difficult to overcome. The artificial limitation of output, which has been encouraged by many labor leaders, and was tolerated during the War period by employers because they could not help themselves, must go. The temporary hiatus in general business is the factory managers opportunity, and he is taking a deep breath and sailing into his house-cleaning with a gust of enthusiasm that is good to see.

In the factories of the country, the era of hiring and firing has returned. Unfilled orders in every field are diminishing, and, as a result, men are being weighed in the balance of performance. The loafer, the slacker, the unskilled, are being weeded out with vigor, and the effect upon the real mechanic and trained man is salutary. Many thousands of unskilled workers from the so-called non-essential industries, who, attracted by the high wages and slack discipline maintained in the shipyards and other branches of the metal trades, found their way to a place on the payrolls as mechanics, are out of a job. As a consequence, the ranks of the waiters in hotels and restaurants are again becoming preponderantly male. Elevator-boys and bell-hops are again masculine, while real machinists are once more operating the tools in the workshops.

Throughout the country, the chief topic of conversation is the condition of the automobile industry, and its allied trades. Here is where the blow has hit hardest, with the possible exception of textiles, and here, may it be remarked, was where inflation was greatest. Attracted by the lure of enormous profits, automobiles and tires have been badly overdone. Sassy Sixes and Snappy Eights, even Nobby Fours sprang into existence overnight. Anybody who could dig up a few thousands and lease a little factory space, could assemble some sort of car, and, aided by bright attractive paint, launch it upon the market and, apparently, get by. It was the same with tires. Akron, the home of the rubber factories, became a great hive of industry. Hardly a week went by that did not herald one or two new brands of cars and tires.

Even the great established concerns responded to the psychological effect of the boom. It was in the air. They took their profits, or what was left of them after the tax-gatherers got through, borrowed more money, built more factory capacity without stint, and so on, *ad lib*, until the bubble was pricked. Now they are facing a ruthless pruning process with the prospect of operating for some time at fifty, or even forty, per cent capacity, to which must be added the necessity of marketing a large overstock of high-cost perishable goods under conditions of a forced sale.

The automobile 'game' was one of the big factors in the wrecking of the labor market for other branches of industry. The Lake Superior copper district was almost depopulated by the insistent demand on the part of the Detroit factories for any old kind of men at fancy prices. The 1920 census, taken during a period that might be called the apex of the boom, shows clearly the migration from the rural districts to the congested manufacturing districts. Now the factories are disgorging the un-

digested mass of 'outside' labor, which is going back to the farm or the mine, as the case may be.

The automobile industry has been a vast consumer of steel in many of its manufactured forms, and, consequently, of all other metals. The deflation process from that angle is going to add to the already large stock of metals, so no great appreciation in the demand for the produce of our mines may be expected until building operations are well under way.

Building construction, during the War, stopped altogether. It was regarded as a non-essential industry, and priority orders placed materials of all kinds for building purposes way down the line, so that it was practically abandoned altogether. The enormous rents now being paid for office and factory space as well as for dwellings in all of our cities and towns are a consequence of the growth in population with no increase in housing facilities for nearly four years.

Building is beginning, timidly in some places, but nevertheless it is well started, and will gather impetus from day to day until it may even generate into a race to see who will be ready first. The wave is well under way in New York city, more so there than anywhere else in the United States, and is working its way westward slowly but surely. Here, then, is the substitute for the outlet of metal products formerly consumed in such large volume by the automobile industry.

Even building construction, as well as nearly everything else, is being retarded as much as possible, by the hope of investors and buyers for lower prices. The National Association of Purchasing Agents, at their annual convention only a few weeks ago, passed a resolution to notify all of their members that in their judgment, all requisitions should be withheld from action until the last minute, in order to take advantage of the general downward tendency of all markets. Copper is in the doldrums, the greatest producers of quicksilver in California have shut-down, the troubles of the gold miner have been discussed fully in these columns, other metals are in sympathetic accord with these same conditions, while the fact that we are still technically at war with a considerable portion of Europe, together with the chaotic conditions still obtaining there, have kept the door to one of the greatest markets for our metals resolutely closed.

In fact, the miner has reached low water small, but the tide is due to turn, and soon. First there is the labor situation, which is improving slowly but surely, for reasons that have already been cited. Then, there is the market, which also is improving by reason of the resumption of building operations, and last, but not least, there is the most encouraging symptom of all, that is the result of the presidential election.

The sweeping victory of the Republican party shows one thing above all artificial issues, and that is a complete repudiation of the Wilson regime and the Wilsonian policies, domestic and foreign. The Republican majority in both houses of Congress is overwhelming, and, at last, after years of chaos, we will have the legislative and

executive branches of Government in accord. Progress is assured. Constructive legislation will follow as a matter of course. We may at least hope for a reasonable economy in the administration of Government affairs, and the disbandment of the numerous War Bureaus with their hordes of clerks and petty officials. The Wilson-McAdoo tendency toward Government ownership and Government interference with business also goes into the scrap-heap, we hope forever.

The iniquitous excess-profits tax, with its destructive effect upon initiative and enterprise, will certainly go, and in its stead will be substituted some form of general sales-tax that will enable the Government to meet its obligations without destroying the source from which taxes flow. And then, Mr. Burleson will no longer be Postmaster-General. But enough of this panegyric.

"Normalcy" is in sight. The world is at last getting down to business. Goods must be manufactured and then sold. The old machinery for selling is being brought out of cold storage, brushed up, cleaned, and manicured ready for the fray. Expense accounts are again subject to scrutiny, and the dollar is not being thrown to the birds as a thing of no consequence. Caution, study, and careful examination is once more being devoted to betterments. The leaders of industry have not been idle during the last year, and much quiet unostentatious preparation has been under way toward the perfecting of sales organizations, methods of distribution, and the other machinery for selling, in order that the commercial machine might be ready and able to function when the time came. Underlying the surface, down-in-the-dumps condition of the stock and security market is the real, solid, sub-stratum of common sense that discerns in present conditions a necessary and beneficial purging of the whole business structure, whereby the artificial unhealthy extravagance of war profiteering has been brought to a head, lanced, and finally cured.

During a trip through Eastern and Middle-Western centres, I did not succeed in isolating one single pessimist. Even those hardest hit, the automobile crowd, for instance, regarded the drastic remedy now being applied as a good thing in the long run, and the real leaders of that industry are satisfied with the survival-of-the-fittest test that is now being applied with ruthless vigor. Money is tight, not scarce, and hard to get even at 8% for preferred short-time commercial loans. The cold blue eye and icy stare of the banker is the portion of those who ask for help for any doubtful enterprise. The custodians of the people's money are sitting tight, waiting to see the inexorable sorting process weed out the lame, the halt, and the blind, and even the best of the industrial leaders are paying fancy prices for money.

What a chance for the investor! The late J. Pierpont Morgan once said that any man who was a bear on the United States would go broke. Investment bankers are issuing charts showing the market tendency of municipal, railroad, and industrial securities and their relative return for the last five or six years. Seven and even eight per cent for first-class securities is the rule at

present prices. With most of us, the situation is one to make us lick our chops hungrily, and think of the story of the man, who, when riding by a great factory remarked, "I could have bought that site for \$5000 ten years ago, and now it is worth a million". His hearer asked, "Did you have the five thousand at the time?" The man did not reply.

In the meantime, watch Mexico. Since Don Porfirio, aged and worn, had the reigns of government wrested from his shaking hands, prospects for development of the resources of our oft-times troublesome neighbor on the South have never been brighter. In fact, the makings of a boom are not lacking. President-elect Obregon is known to be a strong man, a constructive thinker, and is anything but the Gringo-phobe that either Carranza or Villa were. Already many of the mines, idle for years, are making preparations for re-commencing operations, while much quiet unostentatious exploration work is under way looking toward the development of new properties. A number of enterprising manufacturers of mining machinery already have their scouts on the ground examining the field and making reports to their principals.

Unless the outgoing administration shall take action before, recognition of the Obregon regime and the restoration of diplomatic and consular relations will be one of the first acts of the Harding administration. A return of business confidence will quickly follow, and then the rush will be on. Europe will follow suit, unless it accords recognition to Obregon before we do, and there will be a merry scrap for Mexico's trade. Fortunately, the United States leads the world in the manufacture of mining machinery and appliances, and it will be years, if ever, before Europe will be able to compete from the standpoint of either efficiency, delivery, or design. Let us hope that our own people will cinch their advantage and maintain it for all time to come. Before the War, Germany was our chief competitor in that field; she flooded the market with cheap machinery that was attractive in price only, and spoiled many a legitimate sale through her price-cutting policy. Many of our advertisers can remember vividly the time when hammered-steel battery-shoes and dies were sold for as little as 2½c. per pound delivered at west-coast Mexican ports by the Krupp works, and other staple articles such as stamp-mills, centrifugal pumps, and steel tanks for cyanide-plants in the same proportion. There should be no return to this condition, and probably there never will be. Our own people get themselves properly organized to obtain and hold the business.

Nineteen-twenty-one will be a most interesting year. The whole industrial fabric of the Nation will throw off its wartime shackles and go to work, with the intelligent help, let us hope, of the Washington government. The conservation policy that lets our natural resources go to waste will be packed away in moth-balls together with its proponents, and we will see electrical development under way on an unprecedented scale. Hydro-electric power in the United States is still in its infancy, and its future development will go a long way toward solving the coal

and fuel-oil problem. With the removal of the excess-profits tax, and of the consequent stifling of individual enterprise, and at least the substantial modification of the postal-zone system for second-class mail matter, all of those who are helping to build and construct will take fresh heart and tackle the work with renewed vigor.

Rhodesia Broken Hill

Operations of the Rhodesia Broken Hill Development Co. are discussed in a recent issue of the 'South African Mining and Engineering Journal'. Edmund Davis is quoted as saying:

"We have, as you know, various deposits, some rich in zinc and others containing lead and zinc ores of about similar percentage, but our principal work has been devoted to the production of lead, which is the easiest and earliest profit-earning part of our enterprise. We have not only the two smelters taken over from the Rhodesian Lead & Zinc Syndicate, but we are also erecting two more, one of which we think it may be necessary to keep in reserve, in the event of anything unforeseen happening in the operating of the plant. Our present work consists in the first instance of the development and production of lead ores at No. 1 kopje, and secondly, the general prospecting of our mineral area, and in particular the proving of reserves of zinciferous ores. The result of the work so far carried out on No. 1 kopje has been the proving of a main orebody of very high-grade lead ore, increasing in area and maintaining its richness to 150 ft. below the surface. Below this depth the deposit appears to be split by a ridge of dolomite and at least two orebodies exist below the central part of the workings to a considerable depth. It is satisfactory to note that boring has not yet shown any limitation in depth in the orebodies, the prospects of further continuance beyond the depths so far reached being good. In addition, the boreholes have shown that a large body of zinc ore exists in the vicinity of this kopje, a marked tendency being shown for the replacement of lead by zinc, which should simplify treatment. As far as depth is concerned, ore has already been struck at two points at a depth of 300 ft., these points being 250 ft. apart. In the course of development it became necessary to keep not only the present plant, but the additional furnaces supplied, to make provision for draining the mine at a faster rate than previously, and sufficient additional pumping-plant is being supplied. Summarizing the estimate of ore from the main bodies so far proved, shows about 210,000 tons, averaging 24% zinc, 2½% lead, and ½% vanadic acid, and about 305,000 tons averaging 27% zinc, 10% lead, and between ½ and 1% vanadic acid, these estimates being in no case based on anything below a depth of 100 ft. It is well known now that the main ore deposits are not of a superficial nature, and we are advised that, owing to probable bulges in orebodies, the known existence of ore below the depth used for basing the estimates referred to, and the probable existence of large quantities below this depth, this estimate does not approach the total available ore."

National Department of Public Works

*Two outstanding facts which were not anticipated when the public-works movement took shape in April 1919 are (1) that the engineers of the country in good faith started something which they do not now seem inclined to finish, and (2) that the scope of the movement and its ramifications extend beyond all limits written or spoken of at the time.

I am unable to suggest any adequate reason why the original enthusiasm of so many engineers has apparently been reduced to a passing interest. Engineers responded warmly to it in the first instance and it therefore may safely be assumed that they had original and genuine regard for it. No doubt the enthusiasm of many engineers has been cooled, and in some cases their active opposition has been brought about by the very skilful campaign carried on by members of the Corps of Engineers, U. S. Army. We do not complain of such activities of the Army engineers. Their opposition to a public-works department was expected, and we must not be surprised if in the conduct of that opposition they do not neglect to do the very obvious things which we would do if the situation were reversed. Suffice it to say that many of the civilian engineers on whom we counted for support have been won over to the cause of the Army engineers, and as magnanimous opponents we must congratulate the Corps on its achievements.

To summarize as to the prospects for a department of public works: It is my belief that the principle is thoroughly settled in the minds of the public and of a majority of the members of Congress. The important question remaining is the kind of department that we shall have. This involves a discussion of the matter of engineering control of Government operations. Shall it be civil or military?

It is easy enough for the thousands of engineers of the United States to assert that engineering work of the Government shall be under civilian control, but it is quite another thing to establish that control. It is not difficult for the civilian engineers of the country to set up the claim that our military engineers are not well-rounded engineers; that they are inbred; that the greater part of their meritorious performance is done by their civilian assistants who secure no credit therefor; that the Corps of Engineers is an autocracy and therefore unsuited to the control of public operations in a democracy. Even if we assume for the moment that this is true the fact would not dislodge the military engineers from their present commanding position in the civil work of the Government. By constant application and attention to detail these military engineers have, during past years, created in Congress the habit of providing that the U. S. Engineer Corps shall do thus and so, and whenever a civilian engineering organization is designated the first process is to overcome the aforesaid habit.

The engineers of the country must decide speedily whether it be their desire to have military engineers in control of the public-works of the Nation. If the civilian engineers do not bestir themselves and take a sustained and active interest in this matter they will suddenly find that the die has been cast. When government reorganization takes place the provisions made for engineering control will crystallize and will not become mobile again for at least a generation. It all comes down to a question of what the civilian engineers want and what they will work for. They are strong enough numerically and powerful enough in influence to guide the decision if they choose to do so, but they must not entertain the notion that their adversary is asleep.

What is an Army engineer, and what do civilian engineers wish to do with him? He is first of all a gentleman; has high mental qualifications, is schooled in discipline, is well-poised, and is deliberate in his judgments. He is an excellent friend, an astonishingly attractive companion, and a man whose acquaintance is always productive of benefit. He carries himself well and begets confidence especially in legislative halls.

If the testimony of some of the line-officers, some of the engineer-officers, and many of the reserve-officers, be correct, the Corps of Engineers exhibited in the late war the not wholly commendable results of their high state of specialization. This ought not to be so. Our corps of military engineers should be given responsibility and experience in every line of engineering laid open by government activity. They should take their place in the engineering work of the arid lands and the swamps, the highways and the forests, the mines and the laboratory. They should be given the financial and the commercial training necessary to the proper conduct of operations, so that in war exigency they shall be entirely competent to perform all the engineering functions that present themselves. These facts, which it is believed no thoughtful person will deny, bring us to the forks in the road. Shall, by reason of this necessity for broad engineering training, the corps of military engineers be in command of all the Government's public-works function, to the perpetual subordination of the civilian engineers? Or shall they constitute, as was originally intended, a military arm of the Government and be given their training and experience by temporary assignment to positions in civil work; by transfer therein according to plans most advantageous for the acquirement of such diversified experience?

The civilian engineers of the country must decide, and if they are defeated in the forthcoming contest the fact will, in my opinion, be an evidence that the military engineers deserve their success, for it will show that whatever may be their engineering qualifications and however severely their ideals may depart from those which are supposed to constitute the corner-stone of democracy these men do, nevertheless, possess an essential characteristic which the great body of civilian engineers does not, namely, that they know men and are ever vigilant in the exercise of that knowledge.

The Zinc-Oxide Plant of the Utah Zinc Company

By Arthur B. Parsons

INTRODUCTION. Heretofore the nearest market for oxidized zinc ore mined in Utah, Nevada, and the adjacent States, has been at Canon City, Colorado, where the plants of the Ohio Zinc Co. and the Empire Zinc Co. are situated. Both these companies make zinc oxide by volatilizing the metal directly from the ore by means of the Wetherill process. Increased freight-rates in 1918, with the prospect of still further increases, promised to make the marketing of ores of this character still more costly, and it was with the aim of reducing the railroad haul of zinc ore from far Western mines that the Utah Zinc Company undertook the construction of a plant at Murray, six miles south of Salt Lake City. James W.

stopes are caved. This will make the mining of the zinc ore more difficult, but a slicing system is being used that will supply clean ore at a reasonable cost.

The ore from Tecoma is to be the nucleus for the operation of the new plant, which has just been started. The company, however, will purchase suitable ore on a custom basis to serve as a supplementary source of supply. Shipments are being received regularly from various lessees in the neighborhood of Ely, Nevada, and from several districts in Utah. While sulphide ore can be treated by the Wetherill process after a preliminary roast, the Murray plant has no roasters and is not prepared to receive raw sulphide, although by-products from other plants

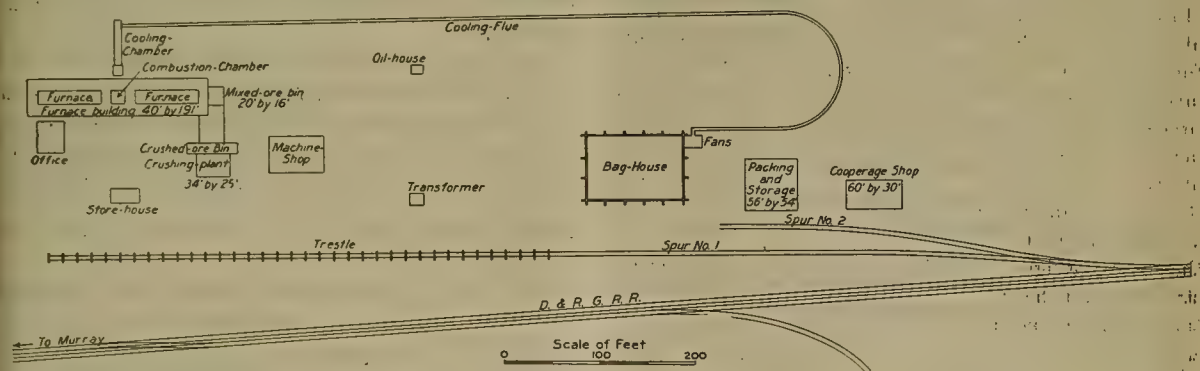

FIG. 1. PLAN SHOWING ARRANGEMENT OF THE BUILDINGS

Wade and associates, who organized the company, were interested in a lease on the property of the Tecoma Consolidated Mining Co. situated 24 miles south-easterly from Tuttle, Nevada, a station on the Tecoma branch of the Southern Pacific railroad, where 30,000 tons of oxidized ore containing 20% zinc and 60,000 tons averaging 16% have already been blocked out. This ore has an unusually low lead content and accordingly is suitable for the making of a lead-free zinc oxide of the kind required in the rubber industry.

The ore deposit originates from the replacement of a stratum of limestone underlain by granite. At the contact the feldspars in the granite have been completely kaolinized, thereby forming an impervious layer along the foot-wall of the zinc deposit. The zinc was originally associated with a body of lead-silver ore that lies immediately above; it was dissolved, however, and re-precipitated in the brecciated limestone, where the impervious kaolin served to concentrate it into a deposit of high-grade ore. There is no well-defined hanging wall; the tenor of the ore gradually increases until at a distance of 100-ft. there is little zinc present.

The overlying lead-silver ore has been mined and the

where the roasting has been done are acceptable. The zinc in the ore may be in the form of carbonate, silicate, or oxide, but it should not contain more than approximately 1% of lead.

USES OF ZINC OXIDE. Zinc oxide is used for two principal purposes, namely, for the manufacture of paint, and as an important constituent in finished rubber goods. In recent years, owing to the rapid expansion of the automobile trade and the increased demand for tires, the rubber industry has outdistanced the paint industry in its demand for zinc oxide. The process for making oxide for either purpose is practically the same. The lead content of the ore is the principal factor in determining the use to which the resulting oxide shall be put. Lead, if present, volatilizes at a lower temperature than does zinc, so that whatever lead is in the ore will be found in the product. In the manufacture of pigments an admixture of lead is not only permissible but desirable; the only requirement is that the lead be entirely converted to the basic sulphate, which is nearly white, and accordingly does not have the effect of discoloring the pigment as would any of the oxides of lead. To effect this reaction it is necessary to provide a combustion-chamber for the

THE ZINC-OXIDE PLANT

hot fume before it enters the cooling-flues. As may be seen from the accompanying drawing, Fig. 3, the furnaces at Murray are provided with such a chamber, so that leady oxide may be made without material alterations in the plant, if at any time it becomes desirable to do so. However, the present intention is to confine the operation of the plant to the manufacture of lead-free zinc oxide for supplying the rubber industry. When added to the mixture of pure rubber and sulphur in the vulcanizing process, zinc oxide acts as a pigment and gives the product its white color. However, the essential function of the oxide is not the whitening effect, but the fact that it has the unique property of increasing the tensile strength of the finished material. George C. Stone gives the following figures, which show the effect on the tensile strength, and the simultaneous diminution in the elongation, produced by introducing varying amounts of oxide.

Zinc oxide added, %	Tensile strength lb. per sq. in.	Elongation, %
25	2400	720
35	2400	700
45	2700	680
55	2500	620
65	2000	540
75	1300	400

In the vulcanizing process lead reacts with sulphur to form lead sulphide; the latter is brittle and translates this property to the rubber. The admixture of more than 0.25% of lead is prohibitive.

THE ZINC PLANT. The Utah Zinc Company selected Salt Lake valley as the site for its plant because of its convenience for transportation. Railroads from all parts of Nevada and Utah converge there. The Denver & Rio Grande right-of-way cuts through the property and a short spur-track grades onto a trestle 400 ft. long, which passes immediately over the ore-bins and stock-piles, while a branch spur serves the packing and storage house for the convenient shipment of the finished product. The accompanying illustration, Fig. 1, shows the general arrangement of the tracks, flues, and buildings.

The crushing department is equipped to crush 150 tons of ore during an eight-hour shift. A 20-in. belt-conveyor carries the ore from under the railroad-trestle to a 10 by 20-in. Allis-Chalmers Blake crusher preceded by a grizzly spaced $\frac{3}{4}$ in. A 16-in. bucket-elevator lifts the crushed product to a $\frac{1}{4}$ -in. square-mesh trommel, the oversize from which gravitates to a set of 14 by 30-in. rolls, of

Denver Engineering Works manufacture, and thence to the foot of the same elevator. The product that passes the trommel goes to a 365-ton crushed-ore storage-bin into which it is distributed by an 18-in. belt-conveyor feeding a 50-ft. shuttle-conveyor at right-angles to it. The course of the ore is shown on the accompanying flow-sheet, Fig. 2.

Hand-trammed ore-cars are filled from the bin and weighed on a Fairbanks platform-scale ready for mixing with coke-breeze that is likewise trammed from storage. A charge composed of the proper proportions of ore and coke, with sufficient water to moisten to a dampness equivalent to that of foundryman's sand, is fed to a 40-ft. Oshkosh concrete-mixer, where it is given five minutes of thorough mixing.

In the Pennsylvanian plants anthracite coal is used for fuel. The characteristics required are high-carbon and low-volatile content, and the fuel should produce the minimum amount of smoke. Bituminous coal is unsatisfactory, but coke, especially if low in sulphur, serves well. Coke-breeze of suitable fineness for use without crushing is obtained at a reasonable cost by the Utah Zinc Company and will be used exclusively.

The mixed product is elevated by means of a second 60-ft. bucket-elevator to the 150-ton mixed-ore bin. A portion of this bin is reserved for coke to be used in forming the bed on the grates of the furnaces. The plan is to do all crushing and mixing during the day-shift, so that night-work will be confined to operating the furnaces and shaking bags in the bag-house. The charge-cars are low and wide with a hinged lip that can be turned down to form a shelf flush with the bottom. The object is to facilitate shoveling from the car. The furnace-building is constructed of concrete and structural steel, with roof and sides of corrugated iron, while the operating-floor is of reinforced concrete.

DESCRIPTION OF THE FURNACE. The general scheme of the furnace is shown in Fig. 3. A good view of the interior of the furnace, taken from the combustion-chamber, shown in Fig. 5. The gates had not been put in place when this photograph was taken. The furnace consists of two sections flanking a central combustion-chamber. Either can be cut-off from the combustion-chamber if required. The concrete foundation beneath each sec-

AT MURRAY, UTAH

tion forms eight individual chambers 9 ft. 2 in. deep and 6 ft. 6 in. by 13 ft. in area. These chambers are filled with water in which any ashes that pass the Wetherill grates accumulate. A $\frac{3}{4}$ -in. feed-pipe, controlled by a valve operated from the charging-floor, supplies cool water just beneath the grate, while the overflow is immediately below the blast-inlet and 14 in. below the grates. The function of the water is to keep the grates cool, thereby preventing warping and buckling, which otherwise would be a continuous source of difficulty.

A water-tight door near the bottom can be removed to clean out the accumulation of ashes, which in time will become sufficient to be troublesome. The grates rest on I-beams, supported by the concrete; an 8-in. blast-pipe enters each chamber just below the grate-level. The arches are lined with fire-brick throughout, while common brick forms the outside walls. The top of the main arch is 8 ft. 6 in. above the top of the grates, while the small arches are 40 in. high and extend $3\frac{1}{2}$ ft. into the furnace. These can be seen clearly in Fig. 5. The series of 'cracks' in the bridge-walls and in the roof of the arch indicate the allowance that is made for expansion when the furnace is heated. The furnace is substantially built and reinforced with buck-stays, of channel and I-beams and $\frac{1}{2}$ -in. rods. A firing or feeding-door is provided for each of the short arches, making 16 doors for each section of the furnace.

The early furnaces using the Wetherill process had doors along one side only, rather than two rows of doors opposite each other. While the present design has the disadvantage that the furnace cools more rapidly, this is probably more than offset by the greater ease with which the accretions can be removed when re-charging is being done. There is, of course, no back-wall and the absence of any obstruction makes the cleaning of the sides and of the grate itself more easy of accomplishment. The grates are cast-iron plates with tapering perforations $\frac{1}{2}$ in. diameter on the top surface, spaced one inch in both directions. The combustion-chamber is a large brick chamber connected on either side by brick passages to the volatilizing sections of the furnace. In the sides of these passages are small arched openings like windows. These are checkered with brick masonry, and removable bricks are provided to permit the regulation of the flow of fresh air into the chamber.

OPERATION OF THE FURNACE. The operation of the furnace, after once being blown-in, consists of drawing and re-charging in rotation at the individual doors. The procedure is as follows: The blast is cut off from the particular division that is to be cleaned and the door opened. The loose part of the last charge is raked off by hand and deposited on the floor to be re-charged later.

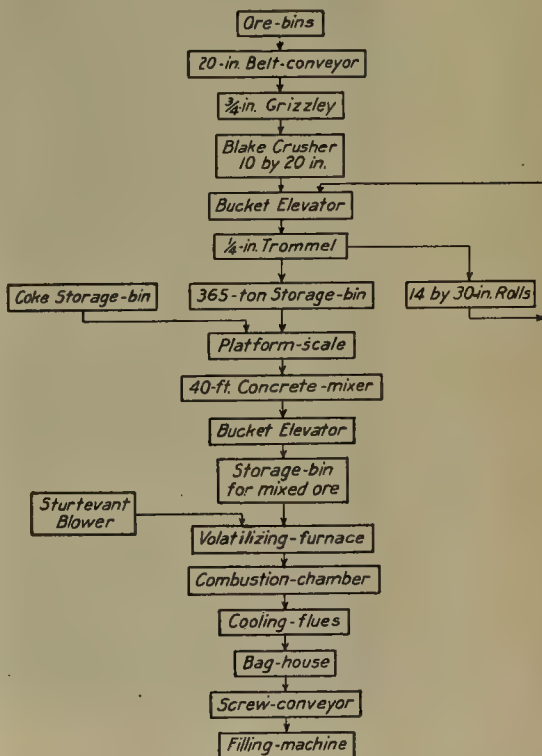

FIG. 2. FLOW-SHEET

The semi-fused clinker is removed in a fashion similar to the cleaning of the fires under a coal-fired boiler, a slice-bar and rake being used for the purpose. The clinker is dropped through a hole in the floor to a car beneath, in which it is trammed to the dump. A layer of fresh coke-breeze is charged on the clean grate and the blast-gate is partly opened. The heat from the hot brick of the arch ignites the fuel and when it is burning briskly the ma-

FIG. 3. ZINC-OXIDE FURNACE, SHOWING TWO OF THE EIGHT SMALL ARCHES ON EACH SIDE OF THE COMBUSTION-CHAMBER.

terial saved from the former charge, with a quantity of mixed ore and coke from the charge-car, is shoveled into the furnace and spread evenly over the bed of fuel. The door is closed and the full blast turned on. The furnace-men then proceed to repeat the operation in the next division, and so continue around the furnace, working the 16 divisions in succession. In the presence of the coke the zinc is first reduced and volatilized; it is then oxidized on coming in contact with the excess of air in the large arch and in the combustion-chamber. A brick downtake conveys the fume-laden gas to a rectangular cooling-flue, also made of brick.

COOLING-FLUE. The blast is supplied by a No. 10 Sturtevant multivane fan with a capacity of 40,000 cu. ft. per minute at a speed of 460 revolutions. The pressure beneath the grate is equivalent to four inches of water. The cooling-flue is a circular sheet-iron pipe 45 in. diameter and 1000 ft. long. It is supported by low bents about five feet above the ground. A shorter flue is undesirable because it does not give the gases sufficient time to cool. Elbows and sharp turns are to be avoided because they offer unnecessary resistance to the flow of the gas. Expansion joints are provided each 30 ft., while at intervals of 8 ft. along the bottom of the pipe are small openings fitted with sliding gates where the oxide that settles may be withdrawn when necessary. The draft, however, is such that this accumulation does not amount to much.

The flow of the mixed fume and gas through the cooling-flue is effected by a 140-in. Sturtevant exhaust-fan situated at the end of the flue near the bag-house. This fan has a capacity of 70,000 cu. ft. per minute at 300 r.p.m. and creates a pressure of $1\frac{1}{2}$ oz. per square foot in the effluent gas. The high temperature of the gas makes it necessary to have the bearings of the fan water-cooled.

BAG-HOUSE. The bag-house is 100 by 70 ft. The floor is of concrete and the foundation is a brick wall 22 ft. high. Surmounting this is the structural steel that forms the upper 19 ft. of the wall, and the trusses of the roof.

At the top is a monitor running the entire length of the structure; it is 9 ft. high with extended eaves to prevent rain from entering the building. The monitor has no sides, and thus provides an outlet for the escaping gases. The accompanying photograph of the plant was taken before the bag-house had been covered.

Ventilation is one of the factors that govern the ratio of bag-area to grate-area; other things being equal, good ventilation will permit a considerably lower ratio.

There are 528 seamless cotton bags, 22 in. diameter

FIG. 4. SECTION THROUGH COMBUSTION-CHAMBER

and 28 ft. high. The fume-laden gas enters the bags from below, the distributing system being the same series of rectangular sheet-iron pipes that serve as collectors for the oxide. The principal header from the exhaust-fan runs along one side of the room; from it, at right-angles, run the distributing pipes, each of which serves a double row of bags. The open ends of the bags fit around circular collars on the distributing pipe while the upper ends are supported by short ropes suspended from a grill-work below the roof-trusses. There are two suspended walks between each two double rows of bags, one at the

level of the distributing-pipe system and the other near the top of the bags. The latter are used by the operators who shake the bags; under normal conditions this is done at intervals of 1 to 1½ hours. The bags are shaken by hand; a mechanical shaker would save labor, but, on the other hand, an experienced man will regulate the amount of shaking of individual bags, and can thereby keep them in more nearly uniform condition.

Satisfactory operation of a bag-house requires that the

condition will in a short time detrimentally affect the furnaces themselves. If the gases cannot escape, the volume and velocity of gas flowing through the cooling-flue decrease, and in a short time the draught to the furnaces will be reduced automatically. This slows the furnace and decreases the capacity with the coincidental poor recovery due to incomplete volatilization of the zinc in the ore. Too little protection also increases the possibility of fire, although in this plant the length of the

FIG. 5. INTERIOR VIEW OF ONE WING OF THE ZINC-OXIDE FURNACE

zinc-oxide fume be separated from the hot gases, the temperature of which fluctuates around 200°C., without excessive deterioration of the cotton cloth of which the bags are composed. To do this it is necessary to permit a coat of oxide to accumulate on the inside surface of the cotton tubing as a protection against the heat. If this coat is too thin the bags suffer; if too thick the obstruction to the passage of the gas is excessive and the amount of fume-laden gas that can be filtered is decreased. This

cooling-flue is sufficient to preclude serious danger from this source. Careful regulation of the shaking, both as to frequency and thoroughness, is necessary to obtain the most satisfactory coating in the bags. A middle course must be taken, there being as much harm if the bags are shaken too frequently and too thoroughly, as if the interval is too long and work too hasty. Regularity is essential; the best operating conditions require that the resistance be uniform at all times.

Dampers are provided to divert the flow of gas from the individual distributing pipes; they are closed in preparation for shaking. The ideal system is to have one set of bags in the process of shaking at all times. The oxide falls into the distributing pipe, the bottom of which is a series of steel hoppers shaped like inverted pyramids, there being one hopper for each four bags. Attached to the hopper is a collecting-sack made of duck, which rests on the floor with its mouth tied around a circular flange at the bottom of the hopper. These bags are detached daily, and with their contents are wheeled to a 9-in. extra-heavy screw-conveyor, which carries the precipitated oxide 70 ft. horizontally to the building where the packing is done. Here the finished product is elevated by means of an 8-in. bucket-elevator to a small storage-bin, from which it is drawn to the packing-machine. This device is borrowed from the flour-mill industry. It is known as the Nardye & Marmon automatic power packer, capable of filling either 50-lb. paper bags or 300-lb. barrels. The packing-house also serves as a warehouse where several thousand barrels may be stored. Railroad-cars are switched on a spur-track alongside this building for convenience in loading.

A cooper-shop where barrels will be made is erected but not equipped as yet. An office-building, a machine-shop, and a store-house for operating supplies, an oil-house, and a transformer-station comprise the other buildings that are completed. I am indebted to James W. Wade, general manager for the company, for his courtesy in permitting these notes regarding the plant to be published.

The Fresno Mine and Mill

The following statement regarding the Fresno mining property in Zacatecas, Mexico, belonging to the Mexican Corporation is abstracted from a letter by William J. Cox to the directors of the Santa Gertrudis Co.: The estimate of 4,000,000 available tons within an area 1000 ft. by 300 ft. and of maximum depth of 200 ft. at the centre of the cone-shaped deposit, does not seem to me to cover a probable tonnage both below the line of estimate and laterally to the south. E. B. Kirby estimates 2,000,000 tons of additional probable ore in further depth, and, knowing him as I do, I have great respect for his judgment. The 'glory-hole' method of extraction of the surface orebody has been planned in every detail, and bears the stamp of approval of engineers eminent in this line of work. Then, too, the character of ground to be broken, the climate, and situation with reference to the point of delivery all appeal to me as naturally adapted to this method. While the mill-site is not ideal, it has advantages of convenient location to the mine, easy excavation, with good base for foundations, and ample area below for storage of tailing, on ground owned by the company. There will be considerable elevating due to little slope of the site, but the arrangement exhibits simplicity.

The foundations are practically finished, except as to the crushing-plant, which is well under way. A brief

description of the ore-flow follows: The broken ore will be drawn from chutes into 10-ton steel cars, and hauled in trains by electric locomotives to the car-tipple at the crushing-plant. In the crushing-plant the ore will be reduced in three passes to $\frac{3}{8}$ -in. maximum size, using one 30-in. gyratory crusher, two 48-in. horizontal and two 48-in. vertical Symon's disc-crushers for this purpose. Thereafter, wet fine grinding to 75% through 200-mesh, will be done in six Marcy-type rod-mills, space being left for the addition of auxiliary tube-mills and for concentration equipment, if found desirable later on, especially in the treatment of sulphide ores. The finely ground pulp will flow to six Dorr-type thickeners, 60 ft. diam. by 10 ft. deep, and thence to 13 agitators of a modified Dorr type, 40 ft. diam. by 25 ft. deep. All these tanks are of redwood, and the great saving in room and cost of construction in the adoption of this type of agitator as against steel Pachuca tanks 15 ft. diameter by 45 ft. high, is to me an outstanding feature. After agitation, the pulp will pass to a Butters-type vacuum-filter plant, the tailing therefrom being pumped to the impounding dams. Precipitation will be accomplished by Merrill zinc-dust method with the recent Crowe vacuum improvement, in an enlargement of the present plant situated safely within the patio walls. Lime will be burned near the mill-site, the stone being hauled about three miles over a good road-bed to the oil-fired kiln. Water is obtained from the deep mine from which it is believed the supply will be ample. Power will be generated in a thoroughly up-to-date steam-plant consisting of oil-fired Stirling boilers, Westinghouse steam turbines direct connected to 60 cycle, 2300-volt alternating-current generators, having a total normal capacity of 6000 kw., with 50% continuous overload rating. This plant should supply ample reliable service for contemplated scale of operations and for future deep mining. The present cyanide plant is treating 400 tons of ore, but the recovery is only fair because of inadequate grinding and agitating equipment. The tailing-plant is yielding a moderate profit from 500,000 tons of residues from the old patio treatment.

SHALE-OIL was formerly produced in southern Germany, but production was killed by American competition. Today the high price of oil and the low exchange make resumption practicable. The production of lubricating oil from brown coal has attained great dimensions. It was begun in 1916 by the German Mineral Oil Co. at the suggestion of Mackensen at a time when the shortage of lubricants threatened to bring the whole war-machine to a standstill. Brown-coal lubricating-oil was first produced on a commercially profitable basis in 1918. The company mentioned has bought up several Central German brown-coal mines and has put up a plant. Particularly good oil is being extracted from the so-called 'resin brown coal' of Thuringia, which yields 32% of tar. In Upper Silesia several companies are making brown-coal oils, and the prohibition against the import of benzine has encouraged production of brown-coal benzine.

A Resume of Literature on the Theory of Flotation, With Critical Notes

By H. R. Adam

*In the following paper I propose to give a summarized version of the theoretical information that has accumulated within the last five or six years in connection with flotation processes for the concentration of ores. Papers on this subject have appeared chiefly in the scientific and technical journals devoted to mining and metallurgy, although it is noteworthy that physicists are now becoming more directly interested. Naturally the written information obtainable on both the practical and theoretical aspects of flotation is still very much scattered and as several important contributions to theory have been published without discussion or criticism it is by no means an easy matter to compare the data available or the statements founded thereon. The matter in this paper is classified not according to dates on which publications have appeared, but according to what have seemed to the writer to be the different phases of the subject, and in adding critical notes he is giving in a general way the results of his own observations and experimental work. For the sake of clearness it was thought advisable to include a good deal of what may be considered by many to be rather elementary and out of date information.

CONDITIONS FOR EQUILIBRIUM WHEN A SOLID IS IN CONTACT WITH TWO FLUIDS. These are the apparent conditions in a mixture of ore particles and water during the application of the various methods of flotation; the ore particles represent the solid, while the fluids are water, more or less modified by the addition of various 'reagents' and gas or gases, the latter in the form of minute bubbles. Before examining the statements of writers on flotation theory under this heading the equation representing the equilibrium as given by Clerk Maxwell¹ should be studied. "The equilibrium of the tensions concerned depends only on that of their components parallel to the surface because the surface-tension normal to the solid surfaces are balanced by the resistance of the solid. Hence for equilibrium,†

$$T_{sg} - T_{sl} - T_{lg} \cos \theta = 0$$

$$\text{whence } \cos \theta = \frac{T_{sg} - T_{sl}}{T_{lg}}"$$

Poynting and Thomson² deduce a similar equation.

Edser³ arrives at a similar result, although in a some-

what different manner. His reasoning is especially interesting, since he assumes that the tension T_{sl} is a residual tension. "When the liquid comes in contact with the solid the surface of the solid will be partly relieved of its strain by the attraction of the liquid molecules and similarly with the liquid molecules. Therefore when wetting takes place $T_{sl} = 0$, e.g., water/glass. When there is absolutely no wetting $T_{sl} = T_{sg} + T_{lg}$ and $\theta = 180^\circ$, $\cos \theta$ in this case being -1 ; such a condition is approached by the contact of mercury and clean glass."

Edser, therefore, assumes that T_{sl} simply depends on T_{sg} and T_{lg} ; this is doubtful, since new conditions may arise on account of chemical or electromagnetic action at the solid-liquid surface or interface.⁴ According to Hatschek⁵ there is no proof that in suspensions T_{sl} can be reduced to zero.

It will be seen from Clerk Maxwell's equation that an increase in the angle of contact means that T_{sl} increases relatively to T_{sg} . If we look at the matter from the aspect of the principle of minimum potential energy it becomes clearer. The greater T_{sl} the greater will be the tendency to reduction in the area of contact of solid and liquid, and it follows that θ will increase; conversely, if T_{sg} is large the tendency will be toward a reduction of the interface solid-gas, which can be done by the spreading of the liquid with consequent decrease of θ .

The following applications of this theory to flotation have been made:

O. C. Ralston⁶ and Corliss and Perkins⁷ state the relationships in the form used by Freundlich⁸ for the distribution of colloidal particles in two liquid phases.

Since Ralston confines his statement to two liquid phases, oil and water, and since in modern flotation it is probably more correct to consider only the two fluid phases "contaminated water" and gas—only the statement according to Corliss and Perkins need be repeated.

These writers state that either

- (1) $T_{sl} > T_{sg} + T_{lg}$
- or (2) No one interfacial tension is greater than the sum of the other two.

They further state that the condition (3) $T_{lg} > T_{sg} + T_{sl}$ is impossible and that case (2) is the actual one in flotation. For complete wetting of gangue, for example, the condition is $T_{sg} > T_{sl} + T_{lg}$; while conditions (1) and (3) would imply complete non-wetting.

This argument is in accordance with the Clerk Maxwell equation, but it must be pointed out that condition (2) implies that a triangle could theoretically be constructed with sides proportional to the three tensions. According to Clerk Maxwell, both experimental work

*From the Journal of the Chemical, Metallurgical and Mining Society of South Africa.

†In order to avoid confusion the symbols used by various writers, which naturally vary, have been put in the one form.

T_{sg} = surface-tension solid-gas.
 T_{sl} = surface-tension solid-liquid.
 T_{lg} = surface-tension liquid-gas.
 θ = the contact-angle.

and theoretical reasoning support the view that this condition is imaginary and where it apparently occurs, one or more of the surfaces is contaminated; that is, where spreading of the liquid does not occur we are not dealing with true contact of the surfaces. It is, however, probably quite justifiable to consider the case in the manner of Corliss and Perkins, since in flotation the surfaces almost certainly are contaminated, but due consideration of the matter is important in view of the discrepancies in the results obtained for contact-angles, to be mentioned later.

Taggart and Beach⁹ state the equilibrium equation as

$$T_{s1} = T_{sg} + T_{lg} \cos \theta \text{ from which}$$

$$\cos \theta = \frac{T_{s1} - T_{sg}}{T_{lg}}$$

This means that a large contact-angle will be the result of a low T_{s1} and relatively high T_{sg} , that is, a tendency for the liquid to wet the solid, which is obviously incorrect. Sulman¹⁰ gives the relationship in the manner of Edser,³ and evidently regards the tension at the solid-liquid interface as a residual tension greater or less according as wetting is partial or complete. Sulman's explanation of the matter is made the more lucid since he discusses the various possibilities according to the variation of the contact-angle between 180° and zero.

In a paper on the theory of wetting, Cooper and Nuttall¹¹ state the equilibrium equation and give a clear explanation of the conditions that may obtain. As these writers have approached the matter from an entirely different standpoint from that of flotation, it is of interest to summarize their article even at the risk of considerable repetition. They quote Quincke as being the first to state the conditions for wetting which, using the same symbols, are:

- (a) That T_{lg} should be low.
- (b) " T_{sg} " " high.
- (c) " T_{s1} " " low.

Cooper and Nuttall emphasize that in regard to wetting it is not sufficient to regard only the surface-tension of the liquid, since even though T_{lg} be high, wetting may occur if T_{s1} is low. The factors influencing T_{s1} are:

(1) The chemical or solvent action of the liquid on the surface layer of the solid; (2) adsorption of dissolved substances at the liquid surface, which occurs when such a concentration causes a decrease in the surface-tension of the liquid. The point made with regard to this adsorption is that it is accompanied by increased viscosity at the surface, and that there appears to be a close connection between superficial viscosity of liquids and their wetting-power for solids; further reference to this will be made in a later paragraph. From the point of view of flotation the value of the work of Cooper and Nuttall lies chiefly in the emphasis laid on the interfacial tension T_{s1} . In the cases which they are considering, namely, the wetting power of dips and insecticides, the possibility of chemical or solvent action at the solid-liquid interface is obvious. In flotation the complexity increases, and we have to consider possible factors influencing T_{sg} and T_{lg} , while the work of Langmuir and Harkins already re-

ferred to indicates that new conditions may arise at the solid-liquid interface affecting T_{s1} .⁵

THE CONTACT-ANGLE. From the foregoing discussion of the equilibrium equation it is clear that the contact-angle is practically the only quantitative guide to the relative tensions. It may be remarked at once that from the practical point of view, measurements of contact-angles are probably of little value in flotation. Even with the utmost precaution against contamination physicists are unable to arrive at close agreement, and it is evident that the most minute alterations in the conditions obtaining at the surfaces of the three phases may affect the angle considerably.

Freundlich⁸ expresses considerable doubt on the question of contact-angles and states that where a positive angle is obtained it may be due only to contamination of the surfaces.¹ He further states that it is generally concluded that complete wetting means a zero contact-angle. In the case of metals, however, the evidence is in favor of a positive angle though the results are in such poor agreement that they can hardly be relied on quantitatively. In the case of glass and water it appears almost certain that if a clean surface is dealt with the angle is zero; for metals Kaye and Laby¹² give the angle as varying between 3° and 11° .

To the writer's knowledge the only two papers on flotation theory giving data on contact-angles are those of Corliss and Perkins⁷ and Sulman¹⁰. The former contributors do not attempt direct measurement of the angles but give the related values of the rise of the meniscus of the liquid against the mineral surface.

For pure water, taking the rise against the surface of the silicate (which silicate is not mentioned) as unity, the rise against chalcocite is 0.5, and for chalcocopyrite 0.8; for 0.1% H_2SO_4 the ratios are, silicate 1, chalcocite 0.6, chalcocopyrite 0.8, and for 0.1% $NaOH$, silicate 1, chalcocite 0.9, and chalcocopyrite 0.9. Corliss and Perkins also found that when the second fluid was an oil-mixture such as is used in flotation, instead of air, the contact-angle of the mineral with the water was over 90° .

The most recent figures for the contact-angles of minerals and water are given by Sulman.¹⁰ It is stated that minerals have a maximum and minimum angle with water and the difference between the maximum and minimum is called the 'hysteresis'. Sulman states that the hysteresis has important effects in flotation. The most noteworthy points in Sulman's investigation are (1) The magnitude of the angles, for example:

	Minimum	Maximum
Stibnite	24.0°	62.8°
Calcite	39.6°	85.5°
Glass	33.0°	39.5°
Quartz	19.5°	58.5°
Chalcocopyrite	37.0°	87.0°
Galena	35.0°	73.0°

(2) The small differences between two such minerals as quartz and stibnite (stibnite is one of the most easily floated sulphides).

(3) The hysteresis—Corliss and Perkins⁷ also refer to this hysteresis and suggest an explanation on the basis of

the smoothness of the mineral surface. Sulman refers to a "molecular interlocking of the liquid and the solid".

In view of the doubt regarding contact-angles, Sulman's figures are distinctly surprising and can hardly be accepted as final, although it is stated that the figures have been confirmed by two different methods. The writer has made several attempts to arrive at satisfactory conclusions for the contact-angles of a few minerals with water. The results obtained were somewhat varied, but, on the whole, indicated that when examination is made immediately after immersion in water the contact-angle is either zero or very small in the cases of chalcopyrite, galena, marcasite, stibnite, quartz, and calcite. The faces examined were, however, not natural cleavage-planes but surfaces obtained by polishing with a fine jeweller's file. There is, however, a distinct difference in the behavior of these minerals. The sulphides only give the zero angle if examined directly after being immersed in water; if the surfaces are merely touched with a piece of filter-paper and then examined again, positive contact-angles up to 90° or more are easily obtained. The inferences is that sulphides 'adsorb' films of air or oxygen with extreme rapidity and in this condition resist the spreading of the water to a greater or lesser extent. It is hoped to give the method of procedure and more detailed results of these investigations at a later date, at present the results are hardly conclusive.

ADSORPTION OF GASES AT THE SURFACES OF MINERALS. Although several writers on flotation—Rickard¹⁸, Sulman¹⁰—have stated that the adsorption of gases on mineral and metallic surfaces is of minor importance in flotation, the evidence in experimental investigations is to the contrary, at least as far as theoretical explanations are concerned. The probabilities are that the tendency which nearly all solids show to condense or adsorb gas on their surfaces is closely connected with the variability of the contact-angle and consequently with the interfacial tensions of solids with liquids and gases. It is true that oil is used in nearly all recent flotation methods, but there is no reason to suppose that this involves great changes in principle since the essential features can easily be manifested without oil. The fact that oil or oils are necessary in practice has tended to obscure the main problem, which is the cause of the preferential adhesion of gas bubbles to sulphides and metals. Unfortunately the knowledge of the causes and effects of gas adsorption on solid surfaces is very limited. Sulman states that "Edser has disproved the air-film theory since such a condensation must involve a considerable quantity of gas . . . readily appreciable by chemical and physical means." He further states that

"(1) Pure air is not condensed to any appreciable extent on blende, quartz, or galena.

"(2) That CO₂ is minutely adsorbed.

"(3) That a gas-free mineral floats at an air-free water surface, that is, in vacuo, with the same ease as at a water/air surface."

These statements are of a controversial nature. It is well known that solid surfaces, particularly metals, do

adsorb or condense appreciable quantities of gases and although this property is not commonly referred to in the specific case of minerals, it is not likely that the latter are peculiar in this respect. In any case there is abundant evidence of a less exact nature that sulphides especially, do adsorb gases readily and that the gaseous films are extremely difficult to remove.

Whetham¹⁴ remarks on "the film of condensed gas which seems to exist on all solid surfaces and to be so difficult to remove". He further refers to the work of Brown, Spiers, and Erskine-Murray, on the effect of such films on the potential difference at the surfaces of metals and electrolytes. "Erskine-Murray has shown that the potential is increased by polishing and reduced by oxidation." Whetham concludes "that there would certainly be less affinity between a gas and a partially oxidized metal than between a gas and a clean metal".

Harkins⁴ states "Since the flotation process depends on the preferential wetting and adhesion of gas films to metals and sulphides on the one hand and silica and similar substances on the other . . ."

Langmuir⁴ refers to the adsorption of gases on solids in connection with the theory that such adsorbed films are in a form of chemical combination with the atoms of the solid surfaces.

Taggart and Beach⁹ refer to the density of gas layers adhering to solids.

In view of such statements as these and many others, it is impossible to dismiss the phenomena as being of minor importance in flotation.

There are several empirical facts of more direct interest to be recorded with reference to this question.

Mickle¹⁵ noted the remarkable pertinacity with which gas adheres to certain minerals. He recorded how zinc and lead sulphides could be made to continue to float by simply heating in water. He assumes that the gas in this case is air and that at each boiling fresh air films are obtained at the surface. Mickle also records similar observations in the case of CO₂ derived from the action of dilute acid solutions on ore particles containing carbonates. He notes particularly the effect of heat on the flotation of sulphide particles by means of CO₂ bubbles. Mickle's work was carried out on zinc and lead sulphides; I have confirmed his results frequently on ore-samples from the Murchison Range district, of the Transvaal, and on Rhodesian gold ores containing antimony sulphide and arsenical pyrite. These investigations, of course, are based on the well-known Potter-Delprat flotation process. If the slightly acid solution in which a mass or froth of sulphide particles has been floated, is allowed to cool, much of the froth will break up and the particles will sink; on heating again the froth will be reformed. In the case of CO₂ bubbles, this can be repeated almost indefinitely although at each heating one notices a tendency for the froth to become less stable. In the case of air, the froth formation is not nearly so permanent, and usually with two or three boilings, wetting appears to be complete. It is difficult to interpret such observations unless we assume that even after repeated boiling there are still adherent films of CO₂ gas. It is possible that after heat-

ing and cooling several times, the bubbles which attach themselves to the sulphide particles consist chiefly of water-vapor. As a result of numerous observations on antimonial ores, however, I am inclined to think that the efficacy of the Potter-Delprat method is chiefly due to the fact that, at or near boiling-point, the gas bubbles are given off in just the right condition for successful flotation—that is—as a continuous stream of innumerable bubbles of minute size, providing a relatively enormous surface and not rising too quickly through the liquid.

Henderson¹⁷, in a paper on flotation at Broken Hill, refers to some recent methods of differential flotation devised by Bradford. These methods have a direct bearing on the question of gas adsorption at sulphide surfaces. It is claimed that by generating such soluble gases as hydrogen sulphide and sulphur di-oxide at the mineral surfaces, air films, which are assumed to be adhering, are selectively removed so that, by small alterations in the acidity and temperature of the liquid, selective flotation can be carried out. It is stated that these methods are commercially successful and they serve to emphasize the importance of gas films in the theory of flotation. In some experiments on the flotation of stibnite ores by CO₂ bubbles, I have found that by passing large air bubbles into the mixture the floating mass of sulphide particles is broken up and the particles readily sink; on heating again the flotation takes place as before, so it is assumed that the effect of the air is chiefly mechanical. According to Freundlich⁸ the nature of the gas is of more importance in determining the amount of adsorption which will take place than the nature of the solid. This is not altogether in agreement with such evidence as is available in flotation investigations, but it may be remarked that Freundlich's statement is apparently based on experimental results on such porous solids as charcoal, meerschaum, etc. The fact that carbon di-oxide is more difficult to remove than air is however in accordance with Freundlich's statement that the more easily liquefied gases are more strongly adsorbed.

FROTHS AND THE EFFECT OF OIL. This phase of the subject has been dealt with very fully by several writers on flotation theory including Rickard¹⁶, Hildebrand¹⁸, Taggart and Beach⁹, and notably Sulman¹⁰. The conditions for a stable froth are clearly set out in works on colloidal chemistry. Lord Rayleigh¹⁹ has shown that frothing is always associated with contamination; in fact, in comparison with other features of flotation the stabilizing of the froths is thoroughly well understood. It is of special interest to note, as has been done by Sulman and others, that the mineral particles themselves may provide the stabilizing conditions; this is what is meant by the term 'armoring' of the bubbles. Thus it may be shown in many cases that when only a small proportion of sulphides is present in an ore these may float but be unable to form a coherent froth since there is insufficient armoring. With an ore-sample containing exactly the same constituents, but a larger proportion of sulphides, a comparatively stable froth may be obtained. Sulman states that the surface-tension of water is considerably

lowered by the presence of mineral particles. If this is correct it may partly explain the fact mentioned by Mickle¹⁵, Henderson¹⁷, and Hoover²⁰, also confirmed by the writer on stibnite ores¹⁶, that the presence of much slime in flotation without oil gives uniformly unsatisfactory results.

It is well known that it is easy to overdo the addition of what are called 'frothers' in flotation and to obtain a 'barren' froth (Sulman, Rickard, Corliss, and Perkins). The reason generally given is that the surface-tension liquid-gas has thereby been so greatly lowered that the wetting tendency is increased. In the discussion on the equilibrium equation, however, it was shown that wetting power depends on other factors than the surface-tension of the liquid, notably the viscosity.

In most of the papers on flotation theory already referred to, the effects of the oil additions are fully discussed. The main effect, although there is no definite evidence on the point, is that the oil spreading rapidly over the sulphide surfaces forms films of extreme tenuity, with the result that the characteristic properties of the sulphide surfaces, as far as the adhesion of gas bubbles is concerned, are so greatly enhanced that practical flotation depends chiefly on these small additions of suitable oils. Sulman gives figures showing greatly increased contact-angles for oil-filmed minerals in 0.7% sulphuric acid.

ADDITIONAL BIBLIOGRAPHY. Owing to the method on which this summary of flotation literature has been prepared the references on the subject cannot claim to be complete.

For much useful information, both on the theory and practice of flotation, the columns of the 'Mining and Scientific Press' for the the last five or six years should be consulted. Most of the articles which have appeared in that journal are collected in a convenient volume edited by T. A. Rickard.²¹ The books on flotation by Hoover²⁰ and Megraw²² also contain chapters on the theory of the subject. The effort required to follow the voluminous reports of legal proceedings over flotation patents is not likely to yield sufficient reward to make it advisable. For a non-mathematical treatment of surface-tension the reader is referred to 'Surface Tension and Surface Energy' by R. S. Willows and E. Hatschek. The most noteworthy contribution to flotation theory which has recently appeared is that by H. L. Sulman, which has been several times referred to. His paper contains a vast amount of valuable information and several portions of it are criticized in the discussion which followed.

Truscott²³ questions the application of the term 'adsorption' to the adhesion of sulphide particles to gas bubbles and the use of the term 'suspensoids' for a mixture of ore particles and water. He questions if there is any fundamental difference between film and froth flotation.

Porter²⁴ criticizes Sulman's idea that a zero contact-angle is not accompanied by complete wetting and questions the extremely high value for the contact-angle water/glass.

Hatschek⁶ criticizes Sulman's statement that complete wetting means a reduction of interfacial tension to zero

and points out that far-reaching conclusions are based on very meagre experimental evidence.

It is impossible to summarize satisfactorily this important paper, but there are portions not already referred to which should be mentioned. Sulman insists on the importance of 'flocculation' in flotation, and states that in order to be floated the mineral must first be 'flocculated'. Flocculation has been considerably studied in connection with the settlement of slime—Free²⁵—but in articles on flotation I have found the term used only in the paper by Corliss and Perkins. The latter, although not very lucid on the matter, apparently conclude that flocculation is harmful in flotation since the aggregates formed may consist of silicious gangue particles which may float with the sulphides. If Sulman's statements are interpreted correctly, however, the trend in flotation practice is to float preferentially almost any desired mineral by causing it to flocculate; this is to be done by various modifying physical and chemical factors. These ideas are in all probability the result of the wide application of flotation to the treatment of 'slime', which is commonly classed as a colloidal solution. The natural inference to be drawn from Sulman's paper is that there are considerable differences in principle between the methods of flotation he chiefly refers to, and what may be called the film-flotation of comparatively large particles which, as has already been mentioned, is best accomplished in the absence of slime. Possibly this theory of flocculation accounts for the fact that the concentrate obtained by the Minerals Separation methods seem generally to contain a high proportion of gangue.²⁶ A further important feature of this paper is the reported effect of acidifying the liquid. It is stated that the contact-angles are generally lower in acid solutions; from this it would probably follow that the surface-tension of water is decreased by the addition of acids. Taggart and Beach confirm this to some extent, but according to Taylor²⁷, also Kaye and Laby,¹² the effect of the acid is to slightly increase the surface-tension of water. The most obvious effects of adding acid, in the writer's experience, are that the sulphide surfaces may be freed from oxide films (this is particularly noticeable in the case of banket ore containing pyrite), and that an additional supply of gas bubbles may be provided in cases where carbonates are present.

CONCLUDING REMARKS. As a result of the commercial success of flotation, many new facts have been learned empirically regarding the physical and chemical properties of surfaces. Exact experimental data are however required before sound generalities can be established. It seems to the writer that a statement such as the following is, at present, as much as is justifiable. A tendency for such surfaces as those of metals and mineral sulphides to adsorb and retain films of gas or grease to a greater degree than the surfaces of substances such as quartz and silicates is generally indicated. Such adsorption, according to the theory of adsorption in liquids, must be a manifestation of greater surface energy in the case of the former substances. Having obtained such films, the solids must be regarded as contaminated, and we no

longer have true contact between the solid and the two fluids; the energy of the solid surface being reduced to a minimum by such adsorption, the surface energy liquid/gas is manifested by a decreased adhesion of the liquid to the solid, with the result that the gas bubbles cling more or less tenaciously to the solid surface. The aggregations or 'flocules' of gas and solid particles thus formed may in certain circumstances sink, but in most cases will rise, owing to the great volume of adhering gas.

If it is true that such metallic surfaces have this greater surface energy, such a fact suggests a connection with the fact that metals and sulphides more readily undergo chemical transformation than quartz, silicates, and oxides generally.

It is somewhat disheartening to the metallurgist on taking up the study of flotation theory to find that the obtaining of experimental data is really a matter for the physical laboratory and that the interpretation of results is by no means easy. Hatschek, in discussing Sulman's work, speaks rather sarcastically of the mass of empirical information imparted and the explanations given of the facts. The assembling and reporting of observations of a purely empirical nature must, however, be of great importance in the construction of a general theory. In actual fact the litigation that has taken place over flotation has, among other things, demonstrated that even among physicists, there is almost complete ignorance as to the real meaning of the phenomena that attend the wetting of a solid by a liquid. Hatschek himself admits this,⁵ and suggests it may be due to "a lack of any important problems involving a closer knowledge of these factors". The fact is, however, that the importance of a theoretical study of the phenomena concerned, is not by any means confined to flotation. The references to Whetham's 'Theory of Solution', and to the article by Cooper and Nutall on 'The Theory of Wetting' in connection with dips and insecticides should make this clear.

There are similar problems involved, in the soldering and welding of metals, in the amalgamation and cyaniding of gold, and of even more direct interest on the Rand they have an intimate bearing on the difficult questions concerned in the settlement of fine floating dust particles underground.²⁸

Recovery of Gold From Black Sand

By JOHN GROSS

***INTRODUCTION.** The Alaska Station of the Bureau of Mines has recently conducted tests on two tailings from black sand which had been treated previously at the Station. The results of this previous treatment have been given in a paper entitled 'Recovery of Gold from Black Sand by Classifier Concentration'.

The gold in these tailings was intimately united with quartz, and was so finely divided that it could not be detected with the naked eye, nor even by panning unless the material was ground. Its fineness is further shown by the assay result, which reported only 12% of the gold content as metallic, whereas the assay of the original sand reported 36% of the gold as 'metallics'. The fact that the gold was in such fine particles, closely united with quartz, precluded further recovery by amalgamation without grinding. On the other hand, the small content present, as well as the lack of grinding appliances at the placer mines of Alaska, made it necessary that the material be cheaply handled if at all. With these facts in mind the experiments described below were undertaken.

COARSE TAILING. This tailing had been obtained by amalgamating the concentrate produced by classifier concentration. The tailing was screened on a 28-mesh screen; the oversize was hand-jigged on a six by six-inch screen, resulting in a concentrate and a tailing; the undersize was passed over a canvas table, resulting in a concentrate and a tailing. The results of this experiment were as follows:

	Weight lb.	Weight oz.	Assay gold per ton	Contents gold oz.	Contents gold %
Jig concentrate	6.2	5.6	26.25	0.0813	36.4
Jig tailing	67.5	61.4	3.46	0.1168	52.3
Canvas concentrate	4.7	4.3	2.13	0.0050	2.3
Canvas tailing	31.6	28.7	1.27	0.0201	9.0
	110.0	100.0	4.058	0.2232	100.0

From these results, evidently a fair degree of concen-

tration may be obtained in the coarser portion but not in the finer. A test showed that the gold in the jig concentrate can be recovered by amalgamation if the concentrate is previously ground, but without grinding, the recovery is negligible.

FINE TAILING. This tailing had been obtained from the concentration of minus 30-mesh material on a canvas table. The tailing was again passed over a canvas table, the aim being to produce a small amount of concentrate. The results obtained are as follows:

	Weight lb.	Weight oz.	Assay gold per ton	Contents gold oz.	Contents gold %
Canvas concentrate	11.4	5.4	9.89	0.0564	46.6
Canvas tailing	198.6	94.6	0.65	0.0646	53.4
	210.0	100.0	1.15	0.1210	100.0

These results show that an additional recovery can be obtained on this material by a second treatment on a canvas table, or probably by the use of a long canvas table. A test showed that an excellent recovery can be obtained on this concentrate by amalgamation in a revolving barrel, but whether barrel-amalgamation would pay on such low-grade material is doubtful.

CONCLUSIONS. These experiments demonstrate that on material of this nature an enriched product may be obtained by hand-jigging the coarser sand and by canvas-table concentration of the finer sand. The enriched product of the coarser sand is worthless unless ground and amalgamated. If produced in sufficient quantity, however, it could be profitably shipped to a smelter. In the placer mines of Alaska the amount of black sand produced by each operator generally is small. Treatment for recovery of any gold not ordinarily obtained by classifier and canvas-table concentration followed by barrel-amalgamation of the resulting concentrates, would be profitable only when handling large amounts of black sand. The gold in the enriched product of the finer sand can be recovered by barrel-amalgamation.

ABOUT 600 tons of cadmium accumulates annually in this country as dusts and residues, by-products of the lead and zinc industries, and about 100 tons of metallic cadmium is recovered from these by-products. If all the cadmium dusts and residues were treated, the output of metallic cadmium would be small in comparison to the 19,000 or 20,000 tons of tin annually used in this country in solder, even if due allowance is made for the fact that one pound of cadmium can replace from three to five pounds of tin. Various formulas proposing the substitution of cadmium for tin in solders are given. On the whole, American experience with cadmium solders is promising, and their use for certain purposes seems fairly established. It is known that solders with 10% cadmium and 10% of tin can be used, and that the cadmium content has frequently ranged as high as 30% with 2% of tin.

ASBESTOS from Rhodesia is of high quality and is much in demand by American consumers. Production in Rhodesia was first reported in 1909 when 272.5 tons was produced while in 1919 the output was 9799 tons.

Re-Opening of the Plymouth Mine and the Results

By W. J. Loring

In 1911 the above property was re-opened by the California Exploration Company, Ltd., which was organized for this special purpose.

During a visit to this country from London in 1911, I was asked by Mrs. Charles D. Lane if I would look into the matter of acquiring a property then optioned to Albert Burch. Subsequently, I took over the option from Mr. Burch, and Messrs. Bewick, Moreing & Co., mining engineers of London, through me as their partner formed the California Exploration Company, Ltd., to which the option was assigned, and work commenced under the able supervision of Mr. Burch, who for several years represented Messrs. Bewick, Moreing & Co. in California.

James F. Parks was appointed superintendent, which position he held, with distinction to himself and satisfac-

tion to his company, up to the time of his death last June.

Unwatering and equipping were commenced late in 1911 and completed on July 30, 1914, at which date the new 30-stamp mill began operations after an expenditure of \$960,000. It will be remembered that war was declared by Great Britain on August 4, 1914, less than one week after the new mill started; therefore, the mine was operated for about three years before the United States entered the War.

The first two years working cost averaged \$2.90 per ton. This first figure has grown steadily until for the first eight months of 1920, the cost, excluding development, has averaged \$4.97 per ton, but, including development, \$5.99 per ton. The total tonnage treated for six years and one month to August 31, 1920, totaled 732,745, from which \$4,035,932 has been recovered. The profit over all expenditure has been \$1,119,581. This latter figure would have been greatly increased if it had not been for war conditions, which increased the cost of operating and retarded development to such a point that it

was feared not many months ago that the mill could not be kept supplied with sufficient ore.

A word about what was found when the water was first taken from the mine. The vertical shaft, known in the early days as the Pacific shaft, was 1600 ft. vertical, and when the California Exploration Company began to unwater the mine, the water was running from the collar of the shaft; therefore, all of the workings were under water. The mine had not been operated for 24 years, but even after this long period of idleness, and taking into consideration, the fact that the main vein of the Mother Lode passed through the shaft just below the 1200-ft. level, no considerable amount of repairing was necessary to reach the 1600-ft. level, which was the bottom of the shaft at that time. About fifty sets of timber in the

THE PLYMOUTH STAMP-MILL

shaft had to be renewed, which cannot be considered excessive under the circumstances.

Examination of the 1600-ft. level disclosed the fact that an eastern cross-cut, 140 ft. long, had intersected the main vein, which had been driven upon 160 ft., without finding any ore. An old winze was discovered below the 1600 level, 75 ft. deep, and the bottom of this winze, upon being cleaned out and sampled, disclosed 28 inches of quartz assaying \$17 per ton. This winze was continued to the 2000-ft. level, all in ore, at which point 160 ft. of drift was completed, all in ore, and at the same time a drift south on the 1600 disclosed 260 ft. of ore similar to that uncovered in the winze, averaging about \$6.35 per ton. In all, about 110,000 tons of ore was reasonably in sight with good bottoms and fairly good ends, on the 1600 and 2000-ft. levels, with an intermediate level at the 1850, all of which averaged around \$6.35 per ton.

It was evident that a zone of enrichment or recurrence of ore had been encountered below the 1600 in the new workings, this being a repetition of the results obtained

in other mines along the Mother Lode, all of which had been sunk to greater depth than the old Plymouth had reached, and all of which had encountered zones of impoverishment and enrichment, and upon this experience I recommended the purchase of this property.

It was considered by some prominent engineers at the time, especially in London, that it was not good policy to purchase a mine with barely 110,000 tons of ore in sight, having a gross value of no more than \$6.35 per ton, and at best not over \$2 profit per ton, but having regard to the records of the other large mines on the Mother Lode, which had encountered, mine after mine, better ground by deeper sinking, it was my opinion that the purchase would be profitable to the shareholders.

The result was that the mine has gone on producing ore profitably until early 1920, when several disappointments were encountered in the nature of several orebodies in the mine giving out at depth; and owing to the fact that labor has been scarce, due to war conditions, the development of the mine was retarded to such an extent that shaft-sinking was slow and for a time it looked as if the mill would have to stop operations about the end of 1920.

By making a special effort to get the shaft down below a poor zone encountered at the 2450-ft. level on the main vein, the shaft was extended from level to level until it reached 3050 ft., but before reaching this point, lateral developments disclosed the fact that one or two of the big ore-shoots had given out, or at least they did not extend to the levels immediately below; and as labor was scarce, it was considered advisable to get the shaft down with all possible speed with the hope of a recurrence of ore on the main vein, which, after all, on the Mother Lode is the one that produces the ore in large quantities when found, and the one vein that is to be relied upon more than the foot-wall veins.

The main vein at the 2450 was poor, at the 2600 unpayable, at the 2750 unpayable, then the shaft was sunk 300 ft. to the 3050, and when the last shot was fired in the sump a small vein across the north-east corner of the shaft was uncovered; it assayed \$52 per ton. The shaft was deepened another ten feet, making it 60 ft. below the 3050 level, which was subsequently opened, from which point a preliminary cross-cut east was driven, and a vein ten feet wide, assaying \$10 per ton was intersected. Then the 2900 level was opened and afterward the 3050 level. The 2900 encountered the main vein, which has been driven upon for some considerable distance, without finding any well-defined ore-shoot, although encouraging assays have been obtained in one or two places.

The 3050 level was opened and the distance between a foot-wall gouge and a hanging-wall gouge represents about 35 ft. Half this distance was veined with quartz, assaying considerably over \$10 per ton. Drifting upon this vein was commenced, going south; it gave out at 40 ft. without being faulted, and it is believed that a shoot of ore will be found southward, in which direction the drift is now being advanced.

Drifting northward, the vein narrowed until it was

only two feet wide, but the assays continued to improve and at 103 ft. the vein is over 12 ft. wide, and the car-samples average considerably over \$20 per ton. Often the daily assays from car-samples will run over \$40 per ton, and face-samples as high as \$80 per ton.

The vein is well-defined, hard, and just as it should be to produce a big orebody, and from its appearance at the present moment the ore is expected to continue for some distance. It must be remembered that this development is proving an orebody of considerably greater value and of somewhat different appearance to anything found on the main vein heretofore, in that it is hard, whereas the main vein has invariably been soft; the gold-contents are considerably higher, and it is anticipated as this vein continues northward it will produce a large tonnage of ore of high grade.

It is intended to sink the shaft 600 ft. during the year 1921, opening up four levels if possible during that time. In order to expedite the opening of additional levels, a winze is being extended below the 3050 level; this will be continued downward, anticipating the various levels when shaft-sinking has reached these various points, as the sinking of the shaft will proceed simultaneously with the sinking of the winze, and for the reason that the orebody is directly east of the shaft, it will be easy to develop because there will be required no long cross-cuts or drifts; therefore, the discovery of this ore-shoot has not only been important to the company, but it has surely been important to the town of Plymouth, which is supported entirely by the operations at this mine, and it also proves the persistence in depth of orebodies on the Mother Lode when geologic conditions are favorable.

No mine on earth could have looked poorer during the first few months of 1920 than the Plymouth Consolidated, and without making an effort to reach the deeper ground in this property it would have closed down and probably have lain idle for a number of years, until somebody with courage came along to re-open the mine on the supposition that prompted the Plymouth Consolidated people to re-open this property in 1911.

The main idea of this article is not for the purpose altogether of eulogizing those connected with the property, or the results obtained for them, but to place on record publicly the results obtained, so that other operators on the Mother Lode may know what has been achieved at the Plymouth Consolidated, thus giving encouragement to those who have encountered poor zones in their mines, and, at the same time, trusting that the encouragement obtained at Plymouth will stimulate other operators to further exertion and deeper sinking.

The Plymouth Consolidated mine has been geologically examined by Oscar H. Hershey, also by F. C. Merritt, both geologists of considerable experience, to say nothing of Malcolm MacLaren, an English geologist of world-wide fame, all of whom pronounce the geologic conditions favorable for the deposition of ore in depth. This advice, together with persistence on the part of the owners, has resulted in the giving of new life to an abandoned mining property.

Canadian Institute of Mining and Metallurgy

The Meeting at Winnipeg

By R. C. Wallace

A year ago there was adopted by the Canadian Institute of Mining and Metallurgy the policy of holding an annual meeting in Western Canada as well as the regular annual meeting in the East. Last November the first Western meeting was held at Vancouver and the second meeting was held at Winnipeg during the last week of October. The papers and discussions were grouped round two central themes, namely, the mining and marketing of Western coal and the extent and development of the metallic resources of northern and eastern Manitoba. As was natural, therefore, Alberta and Manitoba were particularly strongly represented at the convention, but the other provinces of the Dominion, with the exception of the maritime provinces, were also represented by delegates.

Speaking for the province of Manitoba at the opening of the convention in the Fort Garry hotel, the Attorney-General, T. H. Johnson, emphasized the fact that the meeting was being held in a province that had no control over its resources, and invited the members to give serious consideration to the question of the representations now being made by the Province for the control of its mineral and other resources. The same theme was vigorously dealt with by Edward Brown, the Provincial Treasurer, at the closing banquet of the meeting while speaking on 'Provincial Policy and Mining Development'. He stated that no Provincial policy could be inaugurated until the question of the disposal of the resources in the provinces of Manitoba, Saskatchewan, and Alberta was finally settled by the Federal government and that the Province would continue to insist on settlement until such settlement were satisfactorily concluded. With the initiation of large undertakings in the development of the copper industry in the North the representatives of the Province are keenly alive to the necessity of the control of the resources being handed over to the Province before any clear-cut policy of action can be adopted by the Province itself.

In his thoughtful presidential address, O. E. S. White-side emphasized particularly the call for service on the part of the Institute and its members individually in the furtherance of the interests of the mining industry in Canada. He suggested various plans whereby the Institute could prove itself a still more valuable ally to the mining industry by educational propaganda in connection with the industry and its national import to Canada. Particularly to business men, who, in the Middle West, look askance at mining investments, the members of the Institute could serve as authoritative sources of information with reference to the mining industry in any area.

His words were specially applicable to Winnipeg audiences, to whom mining has meant investment in stocks the value of which they were unable to appreciate and who had not been made aware of other and more important aspects of mining investment.

Among the papers relating to Western coal and its utilization, special reference can only be made to a few outstanding features. F. W. Gray, editor of the 'Canadian Mining Journal', in dealing with the part played by Western coalfields in Canadian development, made a forceful appeal to the coal-consumers of Western Canada to view the situation from its national and international aspects. He pointed out that the possession by Western Canada of 15% of the world's coal will inevitably mean the gradual predominance of Western Canada in Canadian political and industrial life and the maintaining of Canada as a whole free from economic, and therefore political, subservience. First-aid work was dealt with by D. Macdonald, who discussed and demonstrated safety apparatus used in the mines of Alberta. The question of the advisability of having a uniform type of safety apparatus throughout the Provinces was taken up and a committee appointed to collect data and make recommendations. H. A. Mackay described the powdered-coal open-hearth furnaces at the Selkirk rolling-mills, in which Western coal is used, and stated that the only difficulty yet to be solved was the protection of the acid lining, which in present practice was to some extent attacked, presumably by the fused dust from the coal. Some questions in connection with the marketing of Western coal were taken up by D. King, while the resources of Alberta in general were exhaustively treated by J. A. Allen, who made some interesting references to the discovery of oil at Fort Norman in the Mackenzie basin, in connection with the possibilities of the province of Alberta and the Northwest Territories as a last great oil-producer of the continent.

With the exception of a paper on the non-metallic mineral deposits of Manitoba by D. C. McArthur, in which he dealt more particularly with the valuable gypsum deposits of the Gypsumville area, the papers and discussion on the Manitoba field dealt exclusively with the copper and gold areas of the Province. F. J. Alcock, who has recently issued, for the Geological Survey of Canada, a map of the Herb Lake district in which is situated the Rex, Bingo, Northern Manitoba, and other developed or partly developed properties, dealt with the gold deposits of that area from the point of view of their relationship to the country-rock and in particular to the parent granite. The Copper Lake area was discussed by J. P. Gordon

who was responsible for the important discovery of last summer. R. C. Wallace described the Flin Flon orebody, its shape and extent, its relationship to the surrounding country-rock and its origin, and took up some questions connected with the future development of this important copper deposit. The Rice Lake district was fully described by J. S. DeLury, who is engaged in the preparation of a bulletin for the Provincial government on that field. A paper had been prepared by R. J. Colony of Columbia University on the interesting area in the vicinity of Bear river in which the petrological similarity to the Sudbury rock-types was fully investigated. G. R. Bancroft, under whose direction the ore from the Mandy mine has been transported to Trail, discussed the mining and the transportation of that ore and gave interesting details of costs in connection with this unusually difficult method of transportation.

Apart from the trip on the last afternoon of the meeting to the Selkirk rolling-mills and steel foundry, by courtesy of the respective managers, Messrs. Deacon and Davies, who afforded an opportunity to see powdered-coal open-hearth and electric-furnace smelting practice, the iron and steel industry was dealt with in two papers: H. E. Knobel discussed fully the utilization of Ontario iron ores for Canadian furnaces and more particularly the policy of establishing an iron and steel industry at the head of the Great Lakes. F. A. Fahrenwald of Cleveland dealt with alloys and more particularly non-corrosive steels, a subject in which he himself is responsible for important discoveries and advances.

The business sessions were well attended throughout, as were also the more popular evening sessions. At the Smoker, interesting moving pictures were shown of water-power resources and scenes in central British Columbia and on the Pacific Coast by R. C. W. Lett and C. F. Attwood. At the second evening session an illustrated talk was given by R. C. Wallace on the history, settlement, and development of Northern Manitoba, while at the banquet, which concluded the proceedings, the speakers included Edward Brown, the Provincial Treasurer, Mayor Gray of Winnipeg, President Lovatt of the British America Coal Co., J. A. Campbell, and T. R. Deacon. Local business men came most closely in touch with the Institute meeting and with the members at a largely attended luncheon given by the Canadian Club at which the main topics of the meeting and their importance to the business men of the city were especially emphasized.

From time to time the question of the regulations dealing with royalty on Federal lands has been up for discussion before the Manitoba branch of the Institute and the parent body. According to Federal regulations, no royalty is to be imposed on copper and allied metals mined on Federal lands until 1921. After that date the amount of royalty to be imposed will be at the discretion of the Governor-General in Council. It has been foreseen for some time that with the development of an important copper-mining industry in Northern Manitoba, the indefiniteness of the clauses relating to royalty would present a difficulty to investors who proposed to embark on

large development projects in northern areas. With the impending development of the Flin Flon orebody this matter has become acute, and a committee was formed at the meeting to discuss the whole question and to formulate a resolution. This resolution, which was passed unanimously, requested that for a further period of ten years, that is, until the beginning of 1931, no royalty be imposed on copper or allied metals produced from Federal lands and that it be now decided on what basis and as far as possible to what degree royalties be imposed after that date. It was felt by the committee and the Institute that the period of time suggested was sufficient to make possible the establishing of a copper industry on a large scale such as at the Flin Flon property and the solving of the metallurgical difficulties therein involved before the State tax became incident, and, moreover, that the declaration of the policy with reference to royalty at an early date would make explicit an item of cost that at the present time is indefinite.

Steam-Electric Project in South Africa

Kimberley and its surrounding mines have long attracted the interest of engineers as a centre for the consumption of cheap power, and the Government Inspector of Machinery for the district in his last annual report says he believes that a scheme is on the tapis to erect a power-station at the Kroonstad colliery, and transmit the electric power generated there through the Orange Free State, by way of Boshof, Koffiefontein, and Jagersfontein, says a recent issue of 'The South African Mining & Engineering Journal'. A line, either direct or branch, will come to Kimberley. Over a year ago a Kroonstad colliery electric-power scheme was suggested, but was then ridiculed by the man who is now doing his utmost to have it carried out. Such a scheme is of first importance to the Kroonstad Colliery Co., whose product, as a steam coal, is of low quality, and therefore cannot hope to compete with the higher-class coal of the country except at points close to the mine. The scheme is capable of expansion, and would, it is thought, be a strong factor, if developed to its full capacity, in liberating much of the latent wealth of this district. There is a plentiful supply of good water available within five miles of the mine, a weir across the Vaal being all that is necessary to ensure the supply of that essential commodity. De Beers Consolidated Mines, Ltd., even on that company's present electric requirements, would consume approximately 8000 kw. New Jagersfontein would require almost as much, as cheap power would be a strong incentive to that company to centralize on a direct-treatment plant to deal with the whole of the ground mined. Koffiefontein Diamond Mine, Blaauwbosch Diamonds, New Eland Diamonds, Roberts Victor Diamonds, all on the route, would, it is thought, require approximately 2000 kw. to satisfy their requirements. An electric railway from Koffiefontein to Fourteen Streams or Vierfontein would be brought within the range of possibility were such a scheme as that under consideration an accomplished fact.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ALASKA

HIGH COSTS AT NOME.

CAPE PRINCE OF WALES. The Lost River Tin Mining Co. has undertaken work on rather a large scale. While the property has been under development for some 17 years, only recently have considerable operations been initiated for the opening of the deposits. The shaft now is down 300 ft. In sinking it was necessary first to pene-

B. Roper, of Nome, states that the production has fallen off chiefly owing to the high cost of transportation. Freight is \$19 per ton, lighterage \$13 per ton, and wharfage \$1.50 per ton. Coal in the yard is \$46 per ton, which makes gold mining practically prohibitive. Mr. Roper, who is interested in dredging, says that operations of this character are going ahead on a large scale where conditions are suitable. Among the miners and pros-

JUNEAU, ALASKA. ACROSS GASTINEAU CHANNEL IS DOUGLAS ISLAND

trate the tundra and afterward the glacial ice, which is some feet thick. The Eskimo laborers are not satisfactory. Those employed in the mine work spasmodically and lately have been becoming more than ever independent because of the high prices to be obtained for the skins of fur-bearing animals. As a fox-skin brings the Eskimo from \$35 to \$40 and as some of them trap as many as from 75 to 80 in a season it is not hard to understand their disinclination to work as miners.

NOME.—Referring to placer mining in Alaska, Milton

pectors interest is being manifested in the possibilities of placer mining on the Siberian coast.

ARIZONA

DEVELOPMENT WORK AT THE IRON CAP PROPERTY.—ARIZONA STANDARD IS BUILDING NEW LEACHING-PLANT.

GLOBE.—The Inspiration Copper Co. has posted notices, effective at once, concerning four contests for prizes in first-aid work, open to all employees of the company, and to be held on or about the following dates: December 1,

1920, February 1, April 1, and June 1, 1921. In each contest there must be at least three contesting teams of six men each, and the prize will go to the team making the best record, providing that a reasonable standard of skill is reached. The prizes will be in the form of a payment of \$5 per month to each member of the winning teams for periods of from twelve to six months. The contests also include the Old Dominion Copper Co. and the International Smelter Co. The shaft at the Iron Cap mine has been sunk to a depth of 1552 ft., with stations cut at the 1400 and 1500-ft. levels. On the 1500-ft. level the Old Dominion vein was found to be 30 ft. wide. The company has not developed the 1400 and 1500-ft. levels yet, as it is the policy to keep ore requirements about two years ahead of mining operations, and that much ore is blocked out already. The concentrator at the Iron Cap is handling about 300 tons per day, the mill not running Sundays.

The International smelter is handling about the same tonnages as in the last few months, its production being dependent on the output of the various mines in the district. New work at the Miami mine is confined to equipping and deepening No. 5 shaft. Mining in the district continues on the same basis as in the past month, and there has been no further curtailment. All operating mines are in good physical condition, and the various managements are following a conservative policy of development and equipment.

KOFA.—The King of Arizona, one of the famous old gold mines of the State, has been taken over by New York interests and re-named the New King of Arizona. During the last few months active development work has been in progress, a good tonnage of ore has been blocked out, and the construction of a mill is being undertaken.

PRESCOTT.—The Philadelphia Mining Co. has taken over the War Eagle Gladiator property at Crown King, on a five-year lease. As the Philadelphia mine is adjacent to this property, it is planned to run a cross-cut tunnel from the Philadelphia into the War Eagle Gladiator vein that will tap the vein at a level several hundred feet below the present deepest workings. The ore contains gold and silver with some copper.

The Arizona Standard Co., whose property is situated about 14 miles north-east of Prescott, is bringing in machinery for a 125-ton leaching plant and power and other machinery for a 250-ton crushing plant. T. J. Carrigan, general manager for the company, said that leaching is coming to be recognized as the best method for handling carbonate and oxide ores. There is a large tonnage of such ore on the property, containing from 3% to 7% copper.

BISBEE.—Small hope for improvement next year in the present copper market was expressed by Walter Douglas, president of the Phelps Dodge Corporation, on his arrival here from New York. Mr. Douglas said that the Phelps Dodge Corporation will undertake no expansion or construction work under present conditions, and that it will be compelled to economize at every possible point in order to continue production.

COLORADO

'NEW' PROCESS TO BE TRIED IN LEADVILLE DISTRICT MILL.—SEVERAL LESSEES WILL WORK DURING THE WINTER AT ROSITA.

ASPEN.—The Etcetera mine on Castle creek operated by the Hurricane Leasing Co. is producing high-grade ore from a flat vein opened by an inclined shaft and tunnel. A 20-ton shipment recently was settled for at \$175 per ton silver-lead content. The property lies west of the main lime contact.

BRECKENRIDGE.—The Blue Flag Gold Mining Co. is installing new equipment in its Laurium mill. The mill-bins are filled and the plant will commence treatment very shortly. Development continues at the mine and a recent examination by the company's engineer resulted in a favorable report as to ore conditions. Work on the placer holdings has included reinforcement of the dam for protection against spring floods. Many companies and lease-operators are laying in supplies for winter operations.

CRIPPLE CREEK.—The new drill-hole in the east end of the district, driven at a 45° incline, is down about 265 ft. in badly fractured ground. Progress is slow. Interesting developments are looked for in the next 500 ft. as the Blovia phonolite dike-system and spurs should be cross-cut by the drill. Important development is in progress at the Vindicator, in virgin territory south and east of the shaft. Small pockets of rich ore have been found and prospects for the opening up of extensive ore-bodies are considered excellent.

The Granite company and its lessees are producing and shipping a good grade of ore to the Golden Cycle mill from the Dillon, Dead Pine, and Upper Granite properties on Battle mountain. Drifting east toward the Cresson, the Blue Flag Gold Mining Co. is prospecting toward the Cresson with promise of soon entering a richer zone. The vein as now broken is a low-grade mill product. The Blue Flag is equipped with a milling plant not in operation at this time. Owing to poor ventilation during the recent heavy snow storms, work in the 1400 and 1200-ft. levels has been temporarily discontinued and is confined to the 800-ft. level.

LEADVILLE.—A new process, controlled by Joseph T. Terry, for treatment of low-grade and complex ores will be tried at the Leadville District mill. Tests made on ores from the Yak tunnel are reported to have resulted satisfactorily. Mr. Terry has, it is claimed, secured right and title to the mill. Recent shipments of silver-gold ore from the Dinero tunnel, in the Sugar Loaf section, have brought settlement at the rate of 150 oz. silver and 0.31 oz. gold for two cars; two cars settled at 37 oz. silver, 0.21 oz. gold, and one car 55 oz. silver, 0.19 oz. gold. Work continues at the Gertrude at Sugar Loaf, but production and shipments to date have been light.

ROSITA.—Work will be continued during the winter by the Palonia Leasing Co. on the Palonia, Twenty Six M. & M. Co. on the '26', Fowler M. & D. Co. on the Annie, and by lessees on the Leavenworth and Pioneer group.

All are former producers of high-grade silver ore. Among the newer properties now operating are the Stevens, Little Jonny, and Sunset. The Palonia was shipping last week. Work is scheduled to continue during the winter months on the properties named.

SALIDA.—The Ohio smelter at this point has been taken over by Eastern interests represented by Everly M. Davis, of New York, who is also identified with the Rawley mine at Bonanza. A tramway will be constructed connecting the Rawley with the D. & R. G. railway at Shirley about 12 miles from Salida, from which point train service will facilitate the delivery of ore at the smelter. Large reserves of silver-copper-lead ore have been developed, assuring a supply to keep the Ohio smelter in operation for a long period.

MICHIGAN

FURTHER WAGE-REDUCTIONS.—WOLVERINE AND MOHAWK INCREASE OUTPUT.

CALUMET.—Following the announcement of the Calumet & Hecla and subsidiary companies of a 15% cut in wages and the closing of the Osceola Consolidated, Osceola branch of the C. & H., White Pine, and La Salle, the management of Mohawk and Wolverine has posted notices of a 15% wage-cut, effective in all departments. The Stanton mines, however, will not reduce their working forces. Instead they will build up their underground department to the pre-war basis. This will absorb some of the several hundred men laid off by the Calumet & Hecla. No announcement of a wage-cut or curtailment has been made by any of the other mines, although it would not be surprising, in view of the stagnant condition of the copper market, if wages were reduced. A reduction of working forces, however, is scarcely looked for by men conversant with the situation. Most of the mines have curtailed as much as possible and further reductions would cause disorganization.

Mohawk and Wolverine are practically the only mines that have no copper at the smelters and prospective business, it is stated, is sufficient to take the output for the next 60 days. If these orders materialize, Mohawk and Wolverine will close the year with no surplus and even on the low market that has prevailed during the past month both mines have at least been 'breaking even'.

The Copper Range mines are carrying about the same surplus as was reported at the end of 1919 and Quincy's shipments have been far below normal. It is estimated that Calumet & Hecla will close the year with 30,000,000 lb. of copper or very close to the surplus reported at the end of last year. Calumet & Hecla has filled most of its current orders and but little business is in sight for the remainder of November, a month in which shipments are ordinarily heavy, for the close of the lake-shipping means that the higher rates for rail-delivery add to the cost of the metal. The company has just shipped 150 tons of ingot bars for export and 350 tons of metal for New England customers, completing its largest orders for the present.

Wolverine and Mohawk 'rock' tonnage has been in-

creasing to such an extent during the past two weeks that the operation of one stamp in the Wolverine mill has become necessary. For the past six months, the combined production of the two properties has been stamped in the Mohawk mill, with one head allotted to Wolverine 'rock'. With the improvement in the labor situation, an increase of about 15% in output has resulted and Mohawk 'rock' now will require slightly more than three heads. Both mines now are operating at about 80% of normal and unless unforeseen events occur, it will be possible to return to normal before the first of the year. Normal production for Mohawk is about 2400 tons of rock daily and for Wolverine, 1200 tons. Mohawk has been down as low as 1800 and Wolverine to 600 tons during the slump in the metal market. It now is the intention to take on more underground men until production is back on the pre-war basis. As soon as the men are taken on and the output warrants it, a second head

LEADVILLE, COLORADO, AND VICINITY

in the Wolverine mill will be started. It is likely that many of the men let out by the Calumet & Hecla will find places at Wolverine or Mohawk.

Wolverine has started the use of a level-scraper in one of its shafts and it is measuring up to the fullest expectations. In fact it is operating so satisfactorily that it is planned to build others. As soon as the underground force is built up to normal, it is the intention to explore several veins, other than the Kearsarge, running through the property. Lodes on the 13th level, west, and the 28th, east, will be opened by drifting. The first is the Kearsarge conglomerate, which revealed traces of copper in a cross-cut. There is no assurance that the vein will be found to have commercial value, but the appearance of it at a point of contact warrants exploration, and the only manner in which the vein can be thoroughly tested is by drifting. On the 28th level two or three lodes were penetrated by a cross-cut. Ten or fifteen feet of drifts were put in each one and one of the veins is believed to have possibilities. The introduction of mechanical scrapers may be a factor in the development of new lodes on Wolverine lands, for it will result in a material reduction in costs and make it possible to mine leaner lodes profitably. There is little hope that either Mohawk or Wolverine ever will be able to use an automatic shovel of large dimensions, for the lode is too flat. Accordingly,

Wolverine at least will confine its efforts to the further perfection of the scrapers only.

Mayflower-Old Colony has completed its west cross-cut, driven from the south drift. It has penetrated the foot-wall trap and a cross-cut now has been started to the east, with the hanging wall as the objective. At a distance of 13 ft. from the drift, the showing is described as very good. The south drift is proceeding intermittently and at a distance of 310 ft. from the shaft exceptionally encouraging mineralization has been disclosed. The raise being put through the conglomerate lode in the cross-cut east from the north drift is still in the formation at a height of 15 ft. The showing thus far on the 1700-ft. level is better in the south drift than elsewhere. If it is finally determined that the ground south of the shaft is commercial, Mayflower will have a long stretch or territory to mine, for the property limits are about a mile south of the shaft and the western boundary is nearly a mile distant.

A test of Gratiot rock is about to be made by the Seneca Mining Co. An initial shipment of 533 tons has been sent to the Baltic mill of the Copper Range Consolidated, where Seneca rock is occasionally stamped. The result of the test will be awaited with considerable interest. Seneca makes a shipment of a few cars now and then during the course of development work and the rock is said to be yielding a satisfactory return.

NEVADA

THE DEVELOPMENT COMPANY RETURNS MILL TO CONSOLIDATED.

EUREKA.—Work in the Locan shaft, on Ruby hill, has been suspended for more than a week, owing to the breaking of one of the cylinders of the big air-compressor. It has been replaced with a new one. At the Eureka-Holly mine ore is being stoped, while the shaft is being sunk deeper. High-grade ore is being shipped to the smelter. The excavation for the new mill has been started 120 ft. north from the main shaft, and the machinery has nearly all been delivered. Four cars of fuel-oil for the semi-Deisel engine at the hoisting-plant have likewise arrived. H. R. Layng, of San Francisco, has arrived in Eureka and has taken charge of the building of the mill at the Holly mine. The ore will be treated by a volatilization method. The company's teams have been hauling ore from the Eureka-Croesus mine to the Eureka-Nevada railroad during the week and will probably continue as long as the weather will permit. The management reports good shipping-ore in the No. 7 and 8 winzes and in the raise on the shale and also good results from prospecting in the adjacent limestone. In the Uncle Sam mine, work is progressing satisfactorily along the main fissure, except that the night shift has been suspended because of bad air. This will be remedied by the installation of air-pipes and the night shift will go on again as usual. The fissure has one wall heavily stained with iron oxide, and at one point on the surface shows some ore, raking toward the face of the drift.

GOLDFIELD.—The Goldfield Development Co. has turned

back to the Goldfield Consolidated Mines Co. the Consolidated mill, which had been held under lease for more than a year, and it is reported that the Development has abandoned all of the big plans for mining and milling that were announced in March 1919 by A. I. D'Arcy, general manager. It appears to be the general opinion in well-informed mining circles on the coast that the Development enterprise has failed and it is said that only enough of the 1000-ton mill will be left standing for possible treatment of the tailing by the Consolidated. The Development has had a short and checkered career, during which it has passed from the heights of promised success to the depth of generally recognized failure. On February 1, 1919, H. G. McMahon, as trustee for a corporation then being organized and later known as the Goldfield Development Co., acquired the properties in Goldfield of the Consolidated, with the exception of the mill, which was taken over later. The company for a short time gave the mines over to sub-lessees and early in March the plans for 'glory-holing' the Combination were announced. The block to be mined was said to be 1000 ft. long, 40 ft. wide, and to extend to the 380-ft. level. The average value of the ore, practically all stope-filling, was estimated at \$5.60 per ton. Later in March an estimate of 1,500,000 tons of ore in this block was made. The cost of putting the mine and mill in condition was given as \$75,000 and the profit to be derived from the 1,500,000 tons of ore was placed at \$3,000,000. The sale of stock was then commenced, a special appeal being made to shareholders in the Consolidated. In June it was reported that L. E. Whicher, of New York, had formed a syndicate and had taken a large interest in the company, which was said to have \$100,000 in the treasury. Many publications, quoting officials of the company, gave optimistic news, and the mill was to have been started on July 1. On June 13 it was announced that Whicher had bought the Florence and had leased the Reilly block to the Development, the officials of which said the block contained 500,000 tons of ore that could be milled with that in the Combination, according to reports published at that time. About this time two blasts were fired in the Red Top in ore that was said to be 300 ft. long, 60 ft. wide, and 165 ft. thick. The average value of 3000 tons said to have been broken in the first blast was made public as \$22.40 and the second was reported to have broken 6000 tons of \$23.80 ore. On August 15 the first ore for the mill was to have left the Laguna shaft. It was in August that D'Arcy, after issuing the report that has since been made the subject of much controversy, resigned as consulting engineer for the Tonopah Divide to give all of his time to the management of the Development. The first apparent difficulty came in September, when the working force was cut during the Tonopah-Divide strike because of "poor financial conditions". This, coming at a time when the company was thought by the public to be well financed, caused wonder, which was entirely relieved when D'Arcy, after a trip to New York with McMahon, announced in November that they had arranged for re-

financing the company. The details of the plan by which the company was to be re-financed were never announced, but it became generally known in the East and on the Pacific Coast that about this time Whicher severed whatever connection he may have had or had planned to have with McMahon and D'Arcy. This he is understood to have done on advice of his engineer, F. Sommer Schmidt. D'Arcy said in a detailed report issued at this time: "Work on mill repair and construction has already commenced. It is 85% complete at the present time for a tonnage output of 650 tons daily. Completion of the other 15% requires only 30 days. Naturally enough, we shall lose no time in reaching a 2000-ton daily output after the mill begins to operate." The "development and construction" expense to October 28, 1919, was given as \$100,000. The cost of increasing the capacity of the mill from 1000 to 2000 tons was estimated at \$205,000. "The management has found it necessary to re-finance the company and it will be able to report to stockholders within a few days that it has arranged the necessary new financing which will permit the carrying out of the full program as outlined." D'Arcy was quoted early in February as saying the mill would start treating 500 tons daily on April 1, but before that date a 3c. assessment was levied because of "adverse financial conditions". A financial statement issued with the notice of assessment, which was delinquent on April 3, gave as \$127,000 the cost of construction, equipment, and mining. Finally the mill was started on June 16 of this year and, after it had operated for less than two months, assessment No. 2 was levied "for the purpose of creating a surplus to meet operating costs up to September 15, at which time returns should well exceed expenses and the operation show a tangible profit". A statement issued with the notice of assessment said that to July 30 there had been delivered to the mill 4800 tons of ore of a gross value of \$9.50 per ton. The net profit was given as \$12,000, but "the major portion of the values now in solution will not be produced in the form of bullion until the final clean-up". Continuing, the statement said: "Promising mine developments continue and I trust that the shareholders approve of our policy of starting milling operations on this small but profitable scale, gradually working up to the fulfilment of our original plans of a large tonnage daily of lower grade ore." This was the last report made by the company. The Deep Mines has suspended operations following labor trouble, but it is said work will be resumed in the spring. Nothing has been heard recently from the Yellow Tiger, which suspended operations shortly after levying an assessment. The present status of the operations may be the end of an interesting chapter of Nevada mining. The Development company, after riding on the crest of good reports, now apparently has passed away without even a eulogy.

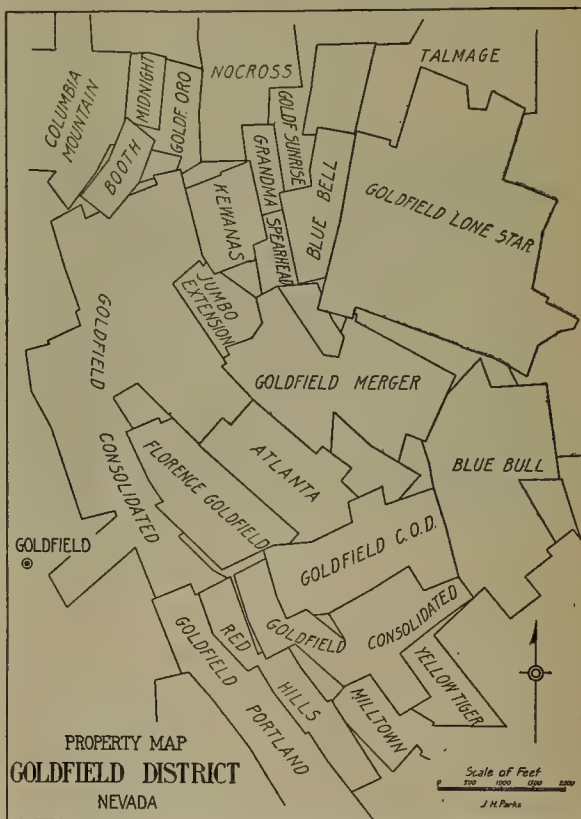

PIOCHE.—The Black Metals Mining Co. has opened a body of high-grade carbonate on the 300-ft. level of the Day mine. Grab-samples of the ore show 30 oz. silver and 15.7% lead. Ore shipments from this district for the week ending November 13 totaled 2760 tons.

UTAH

UTAH COPPER CO.'S REPORT FOR THIRD QUARTER.—NEW ORE FOUND IN EUREKA HILL MINE.

SALT LAKE CITY.—At a meeting of the Utah section of the American Institute of Electrical Engineers on November 16, L. B. Fuller and J. B. Ambler were appointed to draft the proposed State license law for all engineers engaged in public work. The proposed law will be presented to the State Legislature, when it convenes in January, for consideration.

Articles of incorporation have been filed with the

Secretary of State by the Minerals Salt Corporation, the capitalization of which is \$500,000, divided into 5000 shares of a par value of \$100 each. The company owns deposits of sodium sulphate on the south shore of the Great Salt Lake, and a preliminary plant is now being constructed. The products of the plant will be Glaubers salt and salt-cake. The officers of the new company are: R. F. Geoghegan, president; R. H. Jones, vice-president; Lawrence Clayton, secretary; N. W. Clayton, treasurer; E. L. Sheets, A. C. Danie, and Oscar W. Moyle, additional directors.

The Utah Copper Co. has released its fiftieth quarterly report, covering the third quarter of 1920. During that period there was treated at the Arthur plant 1,497,900 dry tons, an increase of 69,300 tons as compared with the second quarter. The ore averaged 1.079% copper and the extraction was 76.57%, as compared with 1.213% copper and 82.8%, respectively, for the preceding quar-

ter. The decrease in heading was due to the large quantity of low-grade ore shipped from the upper steam-shovel levels. The total production of copper for the quarter was 25,331,217 lb., as compared with 29,004,381 lb. for the second quarter. The average cost per pound of net copper produced was 17.156c., as compared with 13.697c. for the second quarter; these costs being exclusive of credits for gold, silver, and miscellaneous income. The value of the gold and silver was \$178,683, and the miscellaneous income amounted to \$153,332. These items combined are equal to 1.377c. per pound of copper produced. The net profit for the quarter was \$502,953, and after the payment of a dividend on September 30, the deficit was \$1,933,781, as compared with a deficit of \$196,265 for the second quarter. The earnings are computed on a basis of 15.791c. for copper; this low carrying price being due to the small sales during the quarter and the increase in copper on hand carried at 13.5c. per pound.

ALTA.—Operations on the Little Cottonwood Transportation Co.'s railroad were suspended on November 15, according to Shand Smith, manager. The railroad runs from Wasatch to Alta. The last three miles of the track to the mines is covered with four or five feet of snow, and the expense of keeping the line open was not justified. During the season, approximately 7000 tons of ore was shipped over the road, practically all of which came from the South Hecla, Michigan-Utah, Emma Silver, Columbus-Rexall, and Sells properties. Owing to weather conditions, the Columbus-Rexall property was able to haul ore only 14 days during October, and none at all during November. The mine force has been kept busy on exploratory work in the meantime. M. R. Evans, general manager for the company, states that ore awaiting shipment at the mine averaged 52 oz. silver, 21% lead, and 4.4% copper, or a net value of about \$70 per ton. Mr. Evans reports that the mine is in excellent physical condition, and that there are a half dozen stopes from which ore of commercial grade can be extracted.

PARK CITY.—At the old Daly mine, now under the control of the Judge Mining & Smelting Co., Oscar Friendly, superintendent, is now mapping out a system of development to explore virgin territory. A clean-up shipment, consisting of 50 tons of spelter, was made by the Judge smelter, after which the employees were transferred to other work. It is reported that the smelter will resume operations in the spring. Shipments from this district for the week ending November 13 totaled 1818 tons, of which the Silver King Coalition shipped 584; Ontario, 519; Judge properties, 500; Keystone, 165; Judge smelter, 50 tons of premium spelter.

Recently a seam of high-grade ore was uncovered in a new portion of the workings at the Park-Utah property, which has been opened to a width of about 30 in. This makes four shoots of ore at this property, ranging in width from one to four feet, all averaging better than 50 oz. silver. The company has an efficient crew of workmen, and will continue development during the winter. At the Ontario property, the new orebody discovered on

the 1700-ft. level has been opened for a length of 80 ft. The ore is understood to be of high grade.

EUREKA.—Recently a new orebody was opened by lessees in the Eureka Hill mine after considerable development work had been done through the workings of the Centennial-Eureka company, which adjoins the Eureka Hill. Four cars of silver-lead ore have been shipped, averaging about \$40 per ton. This ore was found on the 900-ft. level, in close proximity to the New Year channel, which was a heavy producer of high-grade ore in the early days. In the Gemini mine, also adjoining the Eureka Hill, an orebody is being developed at a point 40 ft. below the 900-ft. level, close to the boundary line between the two properties.

During the week ending November 13, the Tintic Standard shipped 46 cars of ore; Chief Consolidated, 37; Dragon, 16; Eagle & Blue Bell, 13; Iron Blossom, 6; Iron King, 5; Victoria, 4; Grand Central, 4; Gemini, 3; Swansea, 3; Centennial-Eureka, 3; Bullion Beck, 1; Ridge & Valley, 1; Tintic Mill, 1 car of bullion, making a total of 145 cars.

For some months past, work has been under way in the east drift on the 900-ft. level at the Apex Standard Mining Co., and the face is now in dolomitic lime. The drift is now about 400 ft. from the shaft, and previous to taking up this work, a drift was sent toward the north, where several bunches of ore were cut. An effort was made to drive a raise from the north drift, but after it had reached a point 40 ft. above the level, work was stopped, owing to the excessive heat.

BRITISH COLUMBIA

INFLUX OF MINERS TO THE SLOCAN AND WINDERMERE DISTRICTS.

STEWART.—H. A. Guess, of the American Smelting & Refining Co., is quoted as saying that the development of the Premier property has disclosed actual ore, and the possibility of a greater tonnage than has yet been proved. Development meets optimistic expectations. He refers to the plans being made to ship over the snow during the winter and stated that the muddy condition of the road during the summer made the transport of ore to the Coast impracticable. Two caterpillar tractors and sleds will be provided as soon as the trail hardens. The water-power plant at the Premier will be in operation in less than a month, permitting the utilization of larger compressors and more rapid progress in the development and exploratory work now under way. The cyanide mill will be completed and in operation early next year.

WINDERMERE.—There has been a considerable revival of mining in this district. E. J. Fader has completed a 600-ft. tramway, connecting the new ore-bunkers with the working tunnel at the Bunyan mine. New bunkhouses that will accommodate 150 men are in course of erection, but, owing to the difficulty of getting supplies during the winter these will not be finished until spring. The ore is taken by 6-ton auto-trucks from the bunkers to the railway at Windermere. About 30 men are em-

ployed at the mine, which is all that can be accommodated at the present time. Australian interests are opening the Isaac mine, at Brisco, and are re-opening the Nip-and-Tuck. From the latter property a considerable amount of ore has been taken, and is being packed to the road for shipment to Trail. The ore is said to assay \$50 per ton. Thomas Masterman is in charge of both properties. The Paradise, at Athalmer, which is the 'stand-by' of the district, has been shipping steadily to Trail for some time past.

MOVIE.—A rich ore-shoot has been opened at the Society Girl mine, and ore is being mined for shipment to the smelter. This property was re-opened only last August, after a prolonged period of idleness. Work will be continued through the winter.

NELSON.—The strike instigated by the One Big Union in the Slocan district last spring has been definitely broken by a flood of unskilled labor pouring into the district from the Canadian prairies. The Noble Five mine, which has been scratching along with between 20 and 30 men now has a full crew of 70 men. Fortunately the company has recently completed its new bunk-house, which, incidentally, is by far the best of its kind in the interior. It is electrically lighted, steam-heated, and contains shower-baths supplied with hot and cold water and an excellent reading-room, so now the company is able to house the new men in a way that is likely to keep them contented. The Rambler-Cariboo, McAllister, Roseberry-Surprise, and Bosun all have full crews, so during the remaining six weeks of the year the Slocan is likely to give a good account of itself. The output of the district this year will be only one-third of what it has been during the last few years. It is unfortunate for the mine-owners of the district that they have not been able to take advantage of the high metal prices, especially that of silver, that has ruled of late. The Associated Boards of Trade of Eastern British Columbia has wired to the Canadian premier to ask the reason for the recent advance in coal and coke prices, and has requested a suspension of the Coal Commissioner's order pending an inquiry. It is stated that the increase in the price of fuels has caused an increase of 50c. per ton in the ore-smelting charge at Trail.

TRAIL.—The feature of recent operations at the smelter has been the increase in the production of the Consolidated M. & S. Co. mines. Out of a total amount of 11,149 tons, received during the first week in November, the company's mines contributed 10,350 tons. The other shippers were: Florence, Princess Creek, 104 tons; Horn Silver, Similkameen, 48; Iron Mask, Kamloops, 46; Josie, Rossland, 286; Knob Hill, Republic, 41; tons; North Star, Kimberley, 173; Sally, Beaverdell, 40; and White Bear, Rossland, 61.

FAIRVIEW.—High-grade ore has been found at the Submarine Extension. The Submarine mine, formerly the Lone Pine mine, is just south of the international boundary. The lode strikes north-east and south-west, and the new discovery has been made on the British Columbia side of the international boundary. Although

details of the new find are not yet to hand, it is said to be the most important discovery that has been made in the district for a long time.

BARKEVILLE.—Representatives of New York capitalists have made an examination of the ground around Williams creek, with a view to testing its dredging possibilities. A thorough test of the ground is to be made by drilling, and if this should give as promising results as surficial tests indicate, a dredge is to be put on the creek next year. Thomas Blair, brother of the well-known merchant, has been prospecting quartz lodes at Prosperpine mountain; a recent assay of ore taken from the bottom of a 17-ft. shaft gave a return of \$17 per ton in gold and silver. It is generally believed here that if a branch line were built to connect with the Pacific Great Eastern

WAREHOUSE AT VICTORIA MINE, SAN LUIS POTOSI

at Quesnel, a distance of only 60 miles, there would be a revival of alluvial-gold mining in this district, as it is generally conceded that there is a considerable amount of ground that could be worked profitably with a dredge, and the branch railroad would enable heavy machinery to be brought in easily.

VANCOUVER.—A matter of scientific, rather than commercial, interest has been the discovery of an 18-in. seam of coal in the heart of the city. While driving a tunnel underneath one of the main traffic arteries the seam was cut, and some workmen have filled sacks and taken the coal home. It is said to burn brightly and give a good heat.

ONTARIO

REPORT OF KIRKLAND LAKE DEVELOPMENTS.—GOVERNMENT TO TEACH PROSPECTORS.

PORCUPINE.—The Dome Mines Co. has increased its working forces by the arrival of 109 Cornish miners brought from England under a four-months contract, which has enabled the company considerably to increase the scope of its underground operations.

Owing to the order-in-council of the Provincial government declaring mining claims on which the tax of five cents per acre had not been paid to be forfeited, a number of claim holders have lost their properties. The most

valuable of these was known as the Little Pet, situated within half a mile of the Dome, on which \$100,000 had been spent in development and the installation of a small mill, which was thrown open and re-staked. It is stated that the owners were unaware of the tax. The action of the Government is strongly condemned in mining circles as likely to discourage investments.

KIRKLAND LAKE.—A special report by Frank L. Culver, president of the Kirkland Lake mine, states that cross-cutting for 110 ft. on the 900-ft. level has picked up an ore-zone 35 ft. in width. Drifting in this zone, on the hanging-wall side, they found ore with assay-gold content in sulphides, running from \$15 to \$42, and in drifting on the foot-wall side free-gold ore, special assays of which yielded \$37 and \$122. Channel assays for 5 ft. across the face of the drift averaged \$52. Ore from this level is now being treated at the mill. The finding of this ore on the 900-ft. level proves the orebody to persist from the 200-ft. level downward for 700 feet.

WEST SHINING TREE.—The management of the Atlas has decided to install a four-drill compressor and undertake development on a more comprehensive scale, including the sinking of the main shaft several hundred feet. The proved mineralized zone has been considerably extended since spring.

COBALT.—By curtailing certain branches of work, the supply of power in the Cobalt district is believed to be adequate to assure operation of the mines throughout the winter. At the time of writing, only one producing mine, the Beaver Consolidated, has closed down. This was due in part to a break in the crusher that, combined with power-shortage, led to a decision to curtail work until repairs are made and to resume at such time as power-supply becomes more satisfactory. The National Mining Corporation (1920), Ltd., has purchased an interest in the White Reserve mine at Maple Mountain in the Elk Lake district. J. B. Tyrrell is consulting engineer in Canada for this corporation, which was incorporated less than two years ago with £2,500,000 paid-up capital. The White Reserve is the first venture of the new company in Northern Ontario. The property will be explored by core-drilling.

During October the Nipissing mine produced \$184,578. This compares with \$225,100 in September, the reduction being attributed to 'power interruptions'. An average of 30 tons of ore is being shipped daily from the Peterson Lake mine. The revenue from this, as well as the re-treatment of tailing, is said to be adequate to finance a scheme of underground exploration and development in the company's undeveloped areas. H. Mills, Minister of Mines, announces the intention of the Department to start prospectors' classes at strategic points in Northern Ontario. W. L. Goodwin of Queen's University will be in charge of the work. Instructors will be placed at each point selected, competent to give an outline course in geology. At the mining schools of Haileybury and Sudbury a beginning will be made early in the new year, and the course will consist of instructions over a period of about two weeks. In centres where high-schools or

collegiate institutes are situated and laboratories are available, blow-pipe instructions will be included. A minimum attendance of ten persons will be necessary in order to justify the holding of a class.

Owing to the Mining Corporation of Canada being involved in the development of the Flin-Flon property in Northern Manitoba, mining interests in Northern Ontario have endeavored to obtain an official statement as to progress. Mr. Ayer, one of the Flin-Flon operators, has made this statement: "We can say that the results obtained from development to date are fully up to our expectations. Considering this fact, the statement of our engineers that the diamond-drilling, on which the original ore-estimate was made, has been very carefully done, lead us to believe that the grade and tonnage of ore on the property will be as high as anticipated."

MEXICO

IMPROVEMENT IN MINING CONDITIONS.

MONTERREY.—Not only have mining operations in Mexico been stimulated by the restoration of peace throughout the country, but the changed attitude of the Government toward the industry is encouraging to the owners of various properties, it is stated here. Several objectionable and oppressive provisions were contained in the decree relating to the operation of mines which was issued by the Carranza government on June 27 of the present year. These provisions, which especially affected foreign mining investments, have been repealed by the De la Huerta government. Americans and other foreigners can now file on mining claims and procure titles to them without jeopardizing their nationality. Another important ruling issued by the new Government is to the effect that taxes on mines that may be delinquent may be paid in installments instead of all at one time. The Government has also recognized as valid tax payments which mine-owners may have paid to different revolutionary factions. In many instances taxes were paid to two or three different political factions in the course of a year. Where this was done the Government has given credit for all such taxes paid. It is expected that comparatively few titles to mines will be declared forfeited for non-payment of taxes during the long revolutionary period. Many American mine-owners have returned recently to their properties after an enforced absence of several years.

While the strike of coal miners in the State of Coahuila is having a serious effect upon the operation of smelters and reduction plants the Government is making every effort to relieve the situation. It has taken over several of the coal mines where striking operatives had prevented the owners from getting out coal, and is shipping considerable quantities of fuel to smelters and other industrial plants. The large smelter of the American Smelting & Refining Co. at Velardena, State of Durango, which was closed during much of the time the different revolutionary and banditry forces were in control of that part of the country, is now running full blast, and has on hand a supply of coke to run it for some time to come.

THE MINING SUMMARY

HOOVER BECOMES PRESIDENT OF FEDERATED ENGINEERING SOCIETIES

The American Engineering Council of the Federated American Engineering Societies was organized at a meeting held in Washington on November 18. Measures will be taken to promote the establishment of a Department of Public Works, creation of a Federal budget system, solution of the transportation problem, and conservation of the country's resources. Washington was tentatively selected as headquarters of the Council which will represent more than thirty engineering societies with a combined membership of more than 100,000. Herbert Hoover, president of the American Institute of Mining Engineers, was elected president. He addressed the convention on the following evening. He said that intermittent employment, unemployment that arises in shifting industrial currents, and strikes and lock-outs were three sources of waste in production.

Intermittent employment might be eliminated at least in part by co-ordination of economic groups, the various industries working together to aid each other. Using the bituminous coal industry as an example, he said the bad economic functioning could be remedied through a concerted effort of the coal-operators, the coal-miners, the railways, and the great consumers to prevent alternate oversupply and shortage.

Present necessary legislation against combinations, he added, makes co-ordination impossible, but he suggested that there be developed "some method of governmental interest, not in governmental ownership, but in stimulation to co-operation in better organization".

Loss of production incident to shifting of workers because of seasonal and short period operations in industry Mr. Hoover said, could be lessened by the expansion and better organization of local and Federal labor-exchanges. Unless such machinery is provided, the individual worker, he said, "is helpless to find the contacts necessary to make this shift".

Strikes and lock-outs would be materially lessened by the universal acceptance and use of collective bargaining, Mr. Hoover declared, adding that he was confident that this principle could be worked out along the lines laid down by the President's second industrial conference, of which he was a member.

ARIZONA

Oatman.—It is reported that a two-foot vein of very rich gold ore has been found on the 600-ft. level of the United American mine. The vein is presumed to be a continuation of that in the Ben Harrison claim of the Tom Reed company, despite the fact that the Big Jim fault was thought to have displaced the vein. The Tom Reed owners could have purchased the United American property for \$2500 some years ago. The high-grade ore has been followed for 10 ft. with no diminution in richness.

CALIFORNIA

Amador County.—Thirty stamps are dropping regularly at the Central Eureka mill and some of the richest ore extracted from the property is being mined on the 3900-ft. level. Mine operations are rapidly approaching normal,

following the withdrawal of power restrictions and an improved labor situation. Prospecting in the upper levels has been resumed.

Calaveras County.—The construction of a new ten-stamp unit at the mill of the Carson Hill Gold Mining Co. has been practically completed and the battery will start in about two weeks. The addition will increase the capacity of the mill to approximately 15,000 tons per month. In October the mill treated 10,500 tons of ore, and operations for the month are said to have netted the company about \$65,000. The ore sent to the plant is averaging more than \$11 per ton, with total operating costs approximating \$5 per ton.—At the Morgan mine development has been carried to a depth of 1750 ft. with new reserves of ore exposed. The deeper work is proving satisfactory. In addition to the large bodies of milling ore, considerable high-grade quartz ore is reported to be in sight.

IDAHO

Coeur d'Alene.—Miners are more plentiful and many of the smaller properties are doing assessment work. The Alma Mining Co. reports that the company intends to resume development. The Jumbo Mining Co. is working on its property in the Murray district and may continue this work in the spring. The Square Deal mine is doing assessment work and has an 800-ft. tunnel. The Tucker Mining Co. has a small force extending the main drift on its property near Mullan. Ten men, working two shifts, are driving a cross-cut in the property of the Brady Development Co. on Nine Mile. They expect to reach the vein in the next 30 feet. The assessment work on the Big Elk, in the St. Joe district, last summer uncovered a big vein of iron-oxide ore containing some silver.

Lessees on the Western Union mine have opened an excellent body of ore. One car that returned \$4000 has been shipped and another is ready. There is no zinc in the ore, which assays 60% lead and 52 oz. silver. While the vein from which the lessees are mining is a rich one, the management of the company does not think it is the main vein and is said to be planning diamond-drill work to cut the main vein at a point 200 ft. north.—Shipments of the Consolidated Interstate-Callahan Mining Co. in October were greater than those of September by about 20%. The figures are as follows: Zinc concentrate, 5,000,000 lb. in October as compared with 4,230,000 in September; lead concentrate, 2,600,000 lb. as compared with 2,180,000, and silver, 26,000 oz. as compared with 21,800 in September.—The Progress Gold Mining Co. in the Murray district of the Coeur d'Alene will continue hand-drilling this winter and in the spring hopes to put in a compressor. A lower tunnel has been started to cut the vein at a distance of 400 ft. At this point on the surface the vein is 8 to 10 ft. wide, with gold content ranging from \$9 to \$76 per ton. The average is more than \$30 per ton. The ore also carries silver and copper.—F. W. Bradley, president of the Bunker Hill & Sullivan Mining & Concentrating Co., after spending considerable time at the smelter and mines at Kellogg, Idaho, says:

"The efficiency of the property is being increased all the time. The smelter has settled down to steady business. The

only addition that will be made is probably a Cottrell treater. This will be used to protect the properties about us and to make greater recovery of lead and silver. Otherwise the plant is as efficient as any plant. We are pushing right along in our experimental work on zinc and are making decided progress, which, we hope, will result, within a reasonable time, in the installation of a zinc-plant annex to our smelter. This is all the more necessary for our district now because other smelters are beginning to refuse to take any zinc ore at all under the present market conditions. The bottom level of the mine is the best we have opened. This level is 1200 ft. below the Kellogg tunnel and 3400 ft. from the surface."—The suit of the Federal Mining & Smelting Co. against the Hecla Mining Co. for \$6,000,000 has been settled, according to Frederick Burbidge, general manager for the Federal company. Mr. Burbidge states that an effort will be made to settle such claims as the Marsh Mines Consolidated may have. The Marsh is the lessee of the ground containing the vein on which an apex claim was made and is an intervenor in the \$6,000,000 suit. The Hecla company is to pay \$450,000 for title to the Russell and Mono fraction claims and a release of all claims for trespass and wrongful extraction of ore.

MONTANA

Deer Lodge.—The new plant of the Champion Mining Co. is nearing completion; it is a 150-ton stamp-mill. Silver is the chief metal, samples having assayed in excess of 100 oz. per ton.

Basin.—The Obelisk Mining Co. recently opened a rich silver vein at its property. The vein has a width of more than six feet and assays 44 oz. silver and 3% lead. It is the intention of the company to install new machinery and work the property on a larger scale than at present.

Butte.—During the month of October the Anaconda company produced 11,000,000 lb. of copper, 100,000 lb. less than in September. The Butte & Superior Mining Co. has suspended operations on account of the unsatisfactory metal market. Some development work in the lower levels of the mine is being done, however, and the organization, except for miners, will be kept intact.

UTAH

Salt Lake City.—A conference of those in charge of the Western offices of the Division of Mineral Resources of the U. S. Geological Survey was held here from November 3 to 8, inclusive. Those present were the geologists in charge of the divisions; G. F. Loughlin, of Washington; Charles G. Yale, of San Francisco; Charles W. Henderson, of Denver; and Victor C. Heikes and C. N. Gerry, of Salt Lake City. James M. Hill, the geologist now attached to the San Francisco office, was also in attendance. The discussions covered the preparation of reports, revision of Western Office blanks, and classification of ores, etc. Questions concerning the proper classification of ores, simple and complex, occupied much of the time, the object being to decide on uniform percentages, fixing certain ores in certain classes, the same practice to be followed in all the offices of the Survey. This will result in more uniform tabular statistics relating to ores in all the States, the questions in doubt having been settled at the conference. The party visited the Utah copper mine at Bingham Canyon and other points of interest in the vicinity.

WASHINGTON

Chelan County.—The Royal Development Co. has begun work on its mining claims on Red mountain, 25 miles north of Leavenworth. Plans of the company are reported to include the building of a railroad from the Great Northern to the property and the construction of a smelter and power-plant.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

H. Hardy Smith is in London.

Ernest G. Ashby, auditor for the Algonquin Development Co., is here from Montreal.

H. G. Nichols is with the Canada Copper Corporation, at Copper Mountain, British Columbia.

George W. Nicolson has resigned as general superintendent of the United Verde Extension mine.

A. G. Cadogan, who has been in a hospital in San Francisco for a month, has recovered and has returned to Cuba.

A. J. Burritt, geologist of Salt Lake City, has been making an examination in the Uintah Basin district in eastern Utah. **Lyman F. Barber** has charge of the construction of the milling plant for the C. O. D. Mining Co., at Kingman, Arizona.

W. A. Barnes, general manager for the Eureka-Holly and Bullwhacker mining companies, is at Eureka, Nevada, from San Francisco.

Charles P. Richardson with **F. Rolandi**, the contractor, is constructing a two-mile tunnel from Hat creek to Pit river at Fall River Mills, Shasta county.

H. S. Mulliken, of Lexington, Massachusetts, has been appointed metallurgical engineer for the Bureau of Mines, and will act as assistant to **F. G. Cottrell**.

Charles W. Henderson, in charge of the Denver office of the U. S. Geological Survey, is visiting the San Francisco office, where he was formerly employed, on his way to his family home in Oregon, while on his annual vacation.

Obituary

Curtis H. Lindley, accounted one of America's foremost authorities on mining law, died on November 20 at his home in San Francisco. He was stricken ill at the conclusion of the trial of an important mining case in Arizona and had returned only two days before. During the War he attained international prominence as the legal adviser of Herbert Hoover; he was an active member of the board of directors of the Panama-Pacific International Exposition. Born in Marysville in 1850, his early life was spent in the mining communities of California and as a boy he developed an interest in mines and miners that was later reflected in his legal practice. His book, 'Mines and Mining', is regarded as the best legal authority on those subjects and has given him prominence throughout the mining world. He was educated at the College of Santa Clara and the University of California, later studying abroad and winning degrees from several universities. He was admitted to the bar in May 1872. A month later he married Lizzie Mendenhall of Santa Clara, who, with one son, Curtis Lindley Jr., and one daughter, Mrs. Vernon S. Rood, survives him. He was appointed secretary of the California Code Commission in the same year. In 1883 he was city attorney of Stockton, and a year later became superior judge of Amador county. After leaving the bench he began the practice of law in San Francisco, where he was associated with Henry Eickhoff. Throughout his career he has frequently been given places of honor by the legal profession. In 1909 he was made president of the State Bar Association. During recent years he has appeared as counsel in mining litigation in many States of the West. He held honorary professorships in the departments of jurisprudence at the University of California and Stanford University and membership in numerous scientific societies.

EASTERN METAL MARKET

(By wire from New York)

November 22.—Copper is inactive and weak. Lead is quiet and easy. Zinc is dull and lower.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48 65 pence per ounce (925 fine), calculated at the normal rate of exchange.

CO-OPERATION AND RECIPROCITY

The whole social order is founded upon the principle of co-operation and reciprocity. If each person will comprehend that the market for his own products or services is dependent upon the ability of others to buy them, he will understand that the largest degree of prosperity for any group or class is obtainable in a state of general prosperity, when production and the exchanges everywhere are well-balanced, says the National City Bank.

It is a reasonable expectation that a readjustment of wages and prices must follow the war period, and it is apparent that this readjustment has begun. The farmers have already taken a heavy shrinkage in the prices of their products. They think it hard that their turn should come among the first, but although the farmer is not a plutocrat, he is a proprietor, an operator upon his own account, and people who have capital enough to be proprietors, he they large or small, are in better position to take the brunt of a readjustment than the wage-earners of the towns. It is impossible to ask the latter to accept wage-reductions until a reduction in living costs has taken place, and farm-products are the leading factor in the cost of living.

On the other hand, the price of farm-products having declined, it becomes a matter of common justice and also an essential factor in the maintenance of employment for the wage-earning class that the prices of what the farmer must buy shall come down in like proportion. Are they going to do so? That is the critical question at this time.

Every one is entitled to have his own opinion of the present industrial situation. A very influential labor leader has declared that labor must "resist, resist, and resist to the last" every attempt to reduce wages, and this is the position which organized labor is understood to occupy. The idea doubtless is that having won the advanced position represented by the present wage-level they intend to hold it at all hazards. It is, however, a mistaken idea, for if prices generally are falling and other people in the industrial circle are taking smaller pay for their services or products the workers who refuse to accept any wage reductions are really asking for more pay. Instead of being on the defensive, trying to hold their own, they are attempting to improve their position at the expense of other workers.

Furthermore, they will be attempting the impossible. They overlook the interdependence of industry. Consider the relations between manufactured products and farm-products. The market for farm products is largely in the towns and the market for the town industries is largely on the farms. About one-third of the people of this country live on the farm. The exchanges are made by means of money payments, but unless farm-products are going to buy about as many town products in the future as heretofore, it does not require a professor of political economy to see that there will be a falling off in the consumption of town products and in the demand for labor to make them. And if 25% of the labor so employed should find itself walking the streets because trade had fallen off, it will be up to the labor leader to explain the advantages of that situation over a moderate reduction of wages which would have kept the farm and factory in balance, with better living conditions for everybody. Goods are not going to be made unless they can be distributed, and distribution cannot occur except upon a fair basis of exchange for all products.

Eastern Metal Market

New York, November 17.

Liquidation of sales of relatively small lots of various metals by some companies or producers in need of cash is the predominating factor in several of the markets. Rather than carry stocks some interests are converting at least a portion of them into cash where prompt or early delivery is involved. This situation has prevailed for some weeks and some markets which had not scraped bottom are lower, such as lead, tin, and zinc.

Copper is a little lower in a dormant market.

Tin has suffered further declines with London prices still falling.

Lead is again lower with consumption showing a decided decline.

Zinc is easier on offerings by interests anxious to sell small lots.

Antimony is lower.

IRON AND STEEL

With buying almost at a standstill, independent steel-company prices are still declining, in a few cases getting to the Steel Corporation level; most blast-furnace and steel-works capacity in all districts is idle, says 'The Iron Age'. Steel Corporation operations hold up to 80% or more, while independent plants are gradually running out of business. In northern Ohio some shut-downs are nearly complete. There is no thought of getting this year an adjustment of prices that will cause free buying and the period of quiet may run some weeks into the new year. To get stocks down to their lowest before January 1 is the aim of all users.

Interest is centring in the prices that the Steel Corporation will announce early in December on sheets and tin plates for the first half of 1921 and on rails for the year.

COPPER

There is a strong belief that the copper market is scraping bottom. Prices have gone a little lower since last week until now electrolytic copper is quoted at 14.75c., New York, for early delivery or delivery this year, with 15c. asked for first quarter. Some sales have been made at these levels, but demand continues small and there is not much life to the market. The lower prices are due to the forces which are referred to above—necessary liquidation by some sellers who do not care or cannot carry heavy stocks. Production is declining and so is consumption, but the cutting down of production at the mines is not as simple a problem as some imagine. While the entire situation is somewhat chaotic there are those who think the copper market has been liquidated. The same authorities hold a similar opinion as to tin and zinc.

TIN

Consumers are still out of the market and so are dealers, and on most days the past week there has been no business. On Monday last week, however, there was a fair volume done in spot and nearby or steamer-at-dock for which around 37.25c., New York, was realized. There was considerable inquiry but it developed that there were few sellers for this position. There has been some activity on the New York Metal Exchange, where about 150 tons was sold, mostly first-quarter shipment, at 38.50 to 38.75c., with one lot of spot Straits, in Pittsburgh, sold under the rule at 37.37½c. Banca tin is scarce and held at about the same level as spot Straits, which yesterday was quoted at 37c., New York, although it fell to 36c. on Monday. The London market was lower yesterday at £238 10s. for spot standard, £240 12½s. for future standard, and £242 for spot Straits, all much lower than a week ago. Arrivals thus far this month have been 2405 tons with 3675 tons reported afloat.

LEAD

This market has gone still lower, the recession being gradual. On Monday the outside market was around 6.40c., St. Louis, or 6.62½c., New York, with the leading interest at 7c., both New York and St. Louis, but very late Monday the latter reduced its price ½c. per pound to 6.50c., both St. Louis and New York. The fact that the official prices are at the same level in both localities is explained on the basis that import lead is still a factor in the New York market. The outside market is now 6.50c., New York, and 6.37½c., St. Louis. On the whole the market is dull and dormant. There has been an increase in supplies with more sellers active for orders. In fact one seller described the market as more of a buyers' market than "in an age". This is due to a falling-off in consumption with almost no improvement in production. Some say liquidation of this market is at an end, while others do not agree.

ZINC

Prime Western for early delivery is quoted today at 6.35c., St. Louis, or about 6.80c., New York, at which levels some sales are recorded. The market is not active but is confined to the immediate needs of some consumers. There have been sales at 6.50c., St. Louis, by some large producers who are not willing to shade this. There are, however, some 'weak sisters' who need the cash and are hence taking such business as is offered, even at a loss. There has been a decided curtailment in production with such companies as Anaconda, Butte & Superior, and others shutting-down their zinc operations. One large seller believes that, when nominal markets again rule, prime Western will sell around an 8 to 9c. level.

ANTIMONY

Spot or early-delivery antimony is again lower, the quotation having fallen to 6c., New York, duty paid, for wholesale lots. Jobbing parcels are ¼ to ½c. higher.

ALUMINUM

The market is inactive and unchanged. Virgin metal, 98 to 99% pure, in wholesale lots for early delivery, is quoted at 32.90c. f.o.b. producer's plant by the leading interest and at 28 to 29c., New York, by other sellers, representing foreign metal largely.

ORES

Tungsten: There is no interest on the part of consumers and no business. Quotations are largely nominal at \$4 per unit for Chinese ore and \$5 for Bolivian. The lower exchange-value is restraining foreign inquiries.

Ferro-tungsten is quoted at 90c. per pound of contained tungsten in guaranteed lump form, and 70c. in unguaranteed. In powdered form the quotation is 78 to 85c.

Molybdenum: Business is at a standstill with quotations nominal at around 75c. per pound of MoS₂ in regular concentrate.

Manganese: The market for high-grade ore is quoted unchanged at 45 to 50c. per unit, seaboard. There is no demand.

Manganese-Iron Alloys: The domestic and foreign producers' quotations for ferro-manganese are unchanged at \$170, seaboard, as a basis, but there is no inquiry to test the market. Re-sale alloy is obtainable at \$150 and it is believed that some British producers would sell direct at \$150, seaboard, if the opportunity should present itself. Spiegeleisen is nominally unchanged at \$75, furnace, for the 19 to 21% grade, with re-sale alloy obtainable at a concession.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE THORNLEY COALOMETER

Coal in storage has the property of spontaneously heating in certain spots and at varying depths. This heating does not always cause actual combustion, in the sense that coal burns with the presence of flame, though this condition is also often found. There does exist almost universally, however, in stored coal of this character a slow combustion, which is even more destructive than combustion by flame, owing to the fact that it cannot be so readily detected, and thus accomplishes its destructive heating, quietly and unnoticed, throughout an ever-increasing zone, beneath the surface of stored coal. This slower escape of the valuable

Head of Thornley Coalometer

fuel, for which the consumer has paid his money, is equivalent to the actual loss of that amount of heating value from fire or other cause. Could the consumer look beneath the surface of his coal pile and definitely acquaint himself with conditions existing there, he could save himself enormous losses by using that part of his coal supply first which showed a tendency to become even slightly heated. In other words, he could burn the heat units which had started to escape before they had done so.

It is for the purpose of indicating these conditions beneath the surface that the Thornley coalometer was designed. It consists of a set of temperature indicators encased in a long pointed steel tube, carrying at varying depths metal bulbs (corresponding to the bulbs of thermometers), and at its upper end a set of indicating dials which show the exact temperatures of the bulbs which actuate them. These units are forced down in the coal pile to definite depths and at various points, and collectively furnish definite data as to the exact temperature existing beneath the surface. If an accurate record of these instruments be kept, periodically, the slightest rise in tempera-

ture is at once detected, and should it become excessive the consumer at once removes this particular portion of fuel, thus saving the heating value of the coal which had started to dissipate.

Tests have shown that one unit at 50-ft. intervals in both directions will efficiently indicate conditions of temperature below the surface. Thus the installation of one triple unit will protect a volume of coal 50 by 50 ft. at its base and of any depth. The cut shows a triple unit Thornley coalometer for use in coal piles from 15 to 20 ft. deep. A galvanized steel tube, having a hardened point at its lower end, carries three bulbs at depths of 5, 10, and 15 ft., respectively. These three bulbs register temperatures in Fahrenheit degrees upon three dials. The scale on each dial starts at 32°F., and is colored black. At and above 120° the scale is red, indicating excessive heat at any point in this zone, and warning the coal man to remove this portion of the coal. The depth of the hot spot is determined at a glance, for the dials are plainly marked 5, 10, and 15 ft., respectively. The dial showing the hottest temperature thus indicates the depth at which the heat is generating.

These instruments are enclosed in weather-tight metal cases with thick crystal faces and the set is mounted in a cast metal case, thus forming one unit. The unit head is shipped separate from its steel stem. Thus, the steel stems are forced into the coal at proper intervals until the surface lugs (so marked) are flush with the surface of the coal pile. After these stems are properly placed, the unit heads are easily attached, and the system is at once ready to show actual temperatures of the coal beneath the surface. Should any unit have to be removed, owing to the indication of excessive temperatures at that point, it is a simple matter to detach the instrument head from the steel stem, and then pull the stem from the coal.

With each set of equipment is furnished a leather-bound loose-leaf record book, each page of which covers seven readings of the indicated temperatures of each coalometer. These records furnish a complete knowledge of the conditions beneath the surface of the coal and enable the manager of such storage equipment readily to determine what portion of his coal is losing its heating value and at what rate. A column on this record sheet shows the exact date at which any unit was removed and the temperature of that portion of the coal at that time. It is easy to figure what losses will occur in dollars in your storage piles, at ever-increasing temperatures and through long periods of time, unless you are constantly posted as to existing temperatures beneath the surface of your coal. The Thornley coalometer was designed to furnish these data at all times with great accuracy.

GREAT THINGS EXPECTED OF NEW TYPE OF AIR-DRILL

The development of pneumatic mining and quarrying tools has been so rapid, and their performance latterly so efficient, that it is but natural they should now be regarded as having reached such a state of perfection that radical changes or improvements are, generally speaking, no longer expected. And yet, notwithstanding this popular notion, the Denver Rock Drill Manufacturing Co. has recently developed

a new type of light mining and quarrying drill which, it is claimed, marks an important advance in the progress of air-drill manufacture. This new drill is built in three models, known respectively as models NA-90, NRW-93, and NRD-95; the first named being a 'dry' auger-drill, especially designed for work in coal, iron, and other soft formations; the second, a combination 'wet' and 'dry' rock-drill efficiently serviceable in all kinds of rock and under all conditions either above or below ground; and the last named, a 'dry' rock-drill particularly adapted to work in wet shafts or where out-of-door conditions prevail.

All three drills are extremely light, so that they can be easily carried about, and each is operated by one man. They are built throughout of the best steels compounded and with the utmost precision. While most Waugh drills are of the valveless type the 'Nineties' are equipped with an en-

New Model Light Air-Drill

tirely new type of spool-valve, having a positive action, which is said to be the last word in simplicity, and efficiency as well. The rotation mechanism is of exceptionally strong design in which stresses in both teeth and pawls are reduced to a minimum.

Lubrication is effected by pulsations of air which gradually feed the oil from a reservoir at the side of the cylinder into all parts of the machine. The manufacturers claim that comparative tests conclusively prove these 'Ninety' drills to be much superior, more powerful, and more efficient, at all pressures, than other drills of their general type and weight, and express themselves as feeling gratified at being able to make contribution to cost reduction in mining and quarrying at a time when the country stands in greatest need of labor-saving improvements in machinery.

COMMERCIAL PARAGRAPHS

L. M. Dozier has become salesman for the Barber-Greene Company; his headquarters being at the St. Louis office of the company.

'G-E Insulating Compounds' is a recent bulletin of the General Electric Co., Schenectady, New York. It is an illustrated description of the many kinds and grades of these compounds, with much general information for their use and handling.

'General Fireproofing' is the title of a periodical publication distributed by the advertising department of the General Fireproofing Co. of Youngstown, Ohio. The August number discusses metal lathe from a number of aspects and is well worth reading by those who are engaged in any building occupation.

Two attractive bulletins recently published by the Pennsylvania Pump & Compressor Co. of Easton, Pa., are entitled 'Pennsylvania Centrifugal Pumps' and 'Pennsylvania Air Compressors'. The features of the design and construc-

tion of the machines made by the company are outlined, while a number of illustrations add to the value of the bulletins.

At a meeting of the directors of the Empire Tube & Steel Corporation, a resolution was passed to have Carl M. Beatrice, president, open negotiations to secure a site which he has had under observation in Buffalo for the purpose of erecting a new plant. It is the purpose of the corporation to install in the Buffalo plant a number of machines that they have in storage, and at the present time have no space to utilize. In this way their business will not be interrupted by the moving of the plant from Long Island to Buffalo.

The new 'Eveready' catalogue, issued by the Oxweld Acetylene Co., of Chicago, Illinois, is now ready for the public. This catalogue is issued in sections, each devoted to a particular phase of 'Eveready' equipment—welding and cutting blow-pipes, regulators, accessories, etc. The 'Eveready' line was formerly manufactured under the name of 'Prest-O-Lite' apparatus by the Prest-O-Lite company, and was extensively used in the metal trades. The Oxweld company took over the production and sales under the present name—'Eveready'—early in 1920, incorporating certain improvements in design lately developed in oxy-acetylene engineering.

It has been the constant endeavor of Holt Manufacturing Co. to build into its 'Caterpillar' tractors those features which will enable the purchaser to realize the greatest possible profit on his investment. Several years ago in studying the needs of the logging industry it was clearly shown that a tractor, to be truly successful, must have incorporated in its design an auxiliary winding-drum or winch-attachment. In the oil-fields this attachment is necessary to pull and run back-rods, tubing, and casings, as well as move equipment from practically inaccessible places. Realizing these requirements, Holt engineers began a study of the application of various commercial winch attachments to 'Caterpillar' tractors, but found them all entirely inadequate. Profiting from experience with these attachments the engineers began the design of a new type of winch attachment embodying those features which are found to be essential to practical operation in the various fields where 'Caterpillar' tractors were used. After several years a 'Caterpillar' winch was developed that met fully the most rigid requirements of oil-field and industrial service. Bulletin C-151 illustrates the application of this winch to various industries and contains a resume of the various specifications that have made it a real success.

Bulletin No. 40017A, issued by the General Electric Co., describes belted, direct-current, continuous-rated generators and exciters, type ML, standardized from 1 to 35 kw., both compound and shunt-wound. When used as exciters they are flat-compounded at 125 volts; otherwise, they are compounded from 115 volts no load to 125 volts full load, unless a shunt-wound machine is desired. Up to and including 9 kw. they are also standard, shunt-wound for 35 volts, for storage-battery service. The armature core, clamped by bolts, is built up of thin steel laminations, carefully annealed, and given a special insulating coating which practically eliminates eddy currents. The coils, form-wound and thoroughly insulated, are protected by end cylindrical flanges. The commutator, of punched rolled copper bars of high conductivity and insulated with selected soft mica, affords commutation without injurious sparking at all guaranteed loads. The pole-pieces are built up of steel laminations slotted parallel to the shaft to minimize eddy-current losses and prevent undue distortion of the magnetic field under load. They are cast-welded to the yoke to minimize field magnetic reluctance. The brush mechanism is the adjustable rocker-arm type. Bearings are ring-oiling. Two slip-rings with brush-rigging and a single-phase auto-transformer constitute three-wire parts.

A Portable Repair Shop

THAT'S what Prest-O-Lite makes of the oxy-acetylene process.

A shop ideally equipped to remake all worn out machine parts—to repair broken castings—to weld practically all metals—and to cut, most economically, all grades of steel and wrought iron.

Thus Prest-O-Lite is of vital importance to the remarkable oxy-acetylene process—the process that has saved millions of dollars in the metal working industries.

Remember—it matters little where the job is, Prest-O-Lite is available—in one cylinder or one thousand.

And our forty plants and warehouses assure practically instant service.

You will be interested in learning more about Prest-O-Lite—the Universal Gas with the Universal Service.

BROKEN HILL is at work again, the strike having ended on November 10. This strike began early in May of last year, so that it lasted more than 18 months, making a most unenviable record. The loss in profits to the mining companies and in wages to the employees is estimated at \$60,000,000. A settlement was effected finally by Judge Edmunds, who was appointed for the purpose by the governments of Australia and New South Wales, the State to which the Broken Hill mining district belongs. The whole affair was as stupid as it was deplorable.

MONEY is tight everywhere. We note that in London the Mexican Corporation offers five-year notes to the amount of £400,000 at 8% and redeemable at a premium of 15%. This corporation is an 'exploration' company organized to acquire and develop mines in Mexico. We note also that the shares of the National Mining Corporation are at a discount of 50%, the quotation being at 5 shillings for the £1 shares on which only 10 shillings has been paid. Presumably the liability of 10 shillings per share is a deterrent to purchase, most people being averse from holding stock carrying an obligation of this kind. The National Mining Corporation was launched a year ago as a consolidation of the most important mine-promoting agencies in London and among its directors are a number of the most influential mining men in the City. It has a capital of £3,000,000 in £1 shares, of which 2,500,000 shares were taken by the directors and their friends, leaving 500,000 shares for subscription by the public. These shares were issued with five shillings paid on allotment and an understanding that calls for five shillings each would be made at intervals of not less than two months. Since then the second call has been made. It is stated that important business is in hand, for which the Corporation will need all the money it can command. We believe that it is looking to Mexico for its principal field of operations.

ON December 1 General Obregon assumed office as President of Mexico. We wish him every success in his greatly important duties as Chief Executive of our neighbor republic and hope that either on the day of his inauguration or soon afterward his government will receive formal and friendly recognition from our government. As a sign of the times, favorable to President Obregon's administration, we note that the striking coal

miners in Coahuila have turned the mines back to their owners, doing this at the order of the Mexican government. The strike began on October 11 and was followed by an entirely unsuccessful attempt on the part of the recalcitrant miners to run the mines themselves. Likewise we note that the workers at the metal mines of northern Mexico are refusing to accept the 'infalsifiable' paper money in payment of wages, asking instead that they be paid in silver pesos. We hope that the Obregon government will accept this as another reason for coining the silver produced in Mexico, which step has been urged by Mr. Charles Butters and is to be recommended for the further reason that it will compel the owners of silver mines to export products other than silver, thereby stimulating the general restoration of industry in Mexico. To the new President we wish good luck. He starts well; he has intelligence, courage, and the intention to do right; he realizes the danger of militarism and the difficulty of creating an honest bureaucracy; he is a soldier and a statesman; he ought to succeed.

FURTHER fall in the quotation of copper shares has followed the continued decrease in the price of metal; in many cases the share quotations are now below the low figures reached on the day after the outbreak of war in Europe, and they are from one-half to one-quarter of what they were at their highest in 1916. Unfortunately some of the American copper sold abroad, in Japan and Europe, early this year, was re-sold later or still remains undelivered. In the first eight months of the current year our exports of copper amounted to 438,875,000 pounds, this being at the rate of 658 million pounds, or 43.8% of the production, which is estimated at 1500 million pounds, or 300 million pounds less than in 1919. Although the copper mines of the United States are operating today at about half-capacity, their output is close to that of the three years preceding the War. What has ruined the market is the lack of big European purchases such as those in the years just before the War when Germany was preparing for the great struggle by accumulating a large stock of metal. At that time exports represented over half of our domestic production; in 1919 exports took only 28.2% of the production. Meanwhile during the War the output was enormously stimulated, so that in 1918 it reached 2432 million pounds, this being an increase of 50% over 1913, the year before the War. In that year we exported 53% of the

copper we produced; last year only 28.2%; this year probably 43%. No real change in the market can be expected until peace is ratified with Germany and economic conditions in Europe are restored to some measure of normality.

EASTERN SIBERIA is a land of fabulous wealth, on the principle of the proverb that says, "The oxen farthest from home have the biggest horns". We know something about that part of the world and therefore were not overwhelmed mentally by the highly colored description of the concession said to have been obtained by the Mr. Vanderlip who was not the Mr. Frank A. Vanderlip of New York but an adventurer from Los Angeles. It appears now that an opportunity of sharing in potentialities of wealth beyond the dreams of avarice was offered to that sagacious old sailor, Capt. Robert Dollar, of San Francisco, a man of keen intelligence and wide experience in business affairs—indeed, one of the merchant princes of the Golden Gate. He declined Mr. Washington D. Vanderlip's offer because he believed that the concession would not be validated in behalf of its American holders, and because any attempt to validate it would lead to war with Japan; moreover, the Soviet government insisted that the widest publicity should be given to the affair in order to swing American sentiment to their side, upon which Capt. Dollar remarked, "There's too much brass band in this". So he relinquished his chance to exploit Kamchatka, a beautiful peninsula delightfully described in Mr. George Kennan's 'Tent Life in Siberia', one of the best books of travel ever written. It seems to us that Capt. Dollar showed characteristic good sense. Meanwhile it is interesting to note, according to recent dispatches from London, that the government of Lenin and Trotzky invites foreign capitalists to assist them in exploiting the resources of Russia, that is, they acknowledge the failure of communism to produce the raw materials needed for domestic manufactures and actually welcome the invasion of foreign capitalism to correct the deficiency.

The Flotation Conference

The recent successful convention of the American Mining Congress at Denver was rendered particularly memorable by a special conference on the present status of flotation, not the state of the art but the conditions created by the tactics pursued by the Minerals Separation company and the unpleasantness ensuing therefrom. Mr. George E. Collins presided, efficiently and gracefully. The proceedings were given point by the presence of three official representatives of Minerals Separation, namely, Mr. Alfred D. Cook, attorney and director, Mr. E. H. Nutter, chief engineer, and Mr. Chester B. Allen, secretary to the Minerals Separation North American Corporation. At the opening session Mr. Collins delivered an interesting address, reviewing the history of the process, with special reference to the Everson episode in Colorado and recording his own early participation in experimental work. Then followed several indict-

ments of Minerals Separation, which was placed in the position of a defendant while gentlemen on the other side fired broadsides loaded chiefly with testimony elicited in the hearings before the Federal Trade Commission; indeed, the 'conference' had the air of a courtroom while two of the lawyers representing the American Mining Congress before the Commission, Mr. George L. Nye, of Denver, and Mr. Gilbert H. Montague, of New York, arraigned the patent-exploiting company. We shall publish their addresses in due course. Mr. T. A. Rickard was asked to speak, but waived the privilege, suggesting that the interest of the proceedings would be heightened if one of the gentlemen on the other side were to reply. Even an opponent could appreciate the unpleasant position of Messrs. Cook, Nutter, and Allen, who had been invited to attend, and who had shown courtesy in coming to the conference, only to find themselves excoriated for their misdemeanors. The chairman invited Mr. Nutter to reply, but Mr. Cook rose to state that they preferred to postpone a response until later, when the attack had been concluded. The afternoon session was marked by an eloquent speech from Mr. Cook, who endeavored skilfully to rebut the evidence adduced against his clients. His statement was interrupted by Mr. Montague, who insisted upon a categorical reply to the question as to whether on the expiration of No. 835,120 the Minerals Separation company would cease collecting royalty from their licensees on the process (less than 1% oil) covered by that patent. Mr. Cook replied that he was not a patent attorney and disclaimed authority to reply to Mr. Montague's question, undertaking, however, to telegraph to Mr. John Ballot, the president of the company, in New York, for an official statement. At the following session, next morning, Mr. Cook read his telegram to Mr. Ballot and the reply thereto. They were as follows:

"Do we claim that if a licensee uses first patent in suit after its expiration in 1923 and operation thereafter does not come under other patents that he must continue to pay royalties to us?"

"The answer to your question is 'No' we do not claim payment of royalty in suit or on any other patent at time of expiration, but we do claim royalty for any other unexpired patents."

Mr. Montague expressed great gratification at Mr. Ballot's telegram, characterizing it as "magnificent" and more than justifying all the efforts made by the American Mining Congress in behalf of flotation users. Mr. Oscar Rohn also expressed satisfaction and remarked that he had no animosity against Minerals Separation. The next speaker was Mr. Nutter, who placed stress on the valuable service performed for the mining industry by his company's testing laboratory in San Francisco and described how he and his associates had persuaded the Anaconda and Inspiration mining companies to adopt flotation, thereby introducing the successful application of the process in this country. A further altercation between the lawyers was checked by the chairman, who called upon Mr. Rickard to speak. He began by saying

that he had not been in any hurry to join in the attack because he had had ample opportunities for doing so elsewhere, and he had availed himself of them freely. He made a plea for intellectual honesty, insisting that without it the conference would get nowhere. He demurred to Mr. Rohn's disclaimer of animosity, insisting that there was plenty of animosity against Minerals Separation, and for good reason. Personally he was much prejudiced against them, but the recognition of his own prejudice did not prevent—it probably helped—him in being fair. As to the "magnificence" of Mr. Ballot's telegram, he thought that interpretation ridiculous; it needed no lawyer to see that the Minerals Separation company could not collect royalty on a patent after it expired and that the expiration of No. 835,120 promised no particular relief because 67 other patents were owned by Minerals Separation. The complexities created by the effort to interpret No. 835,120 were as nothing to the confusion worse confounded that would follow from the impending litigations over the patent for a soluble frothing-agent. As to Mr. Nutter's research laboratory and its usefulness to the industry, it was to laugh. In regard to the first application of flotation to chalcocite ore, it was a fact indeed that the Minerals Separation people had been the first to demonstrate the amenability of this class of ore to flotation, and credit was due to Mr. Nutter personally for this particular achievement, but it was to be remembered that he did this in 1915, that is, nine years after the grant of the patent. The delay in the successful use of flotation in this country was due in large measure to the Minerals Separation company, whose metallurgists had stated in print that the froth-agitation process was not suitable for chalcocite ores. However, he did not desire to belabor the point; it seemed to be about time to recognize the impasse into which the flotation contest had drifted and to endeavor to lift the quarrel out of the morass of litigation. As one wholly detached from personal interest in the matter, he ventured to place a proposal before the conference, namely, that all the patent-rights of the Minerals Separation company be purchased by a syndicate, composed preferably of those representing the principal so-called infringers. Whatever the sum required to make the purchase, a large part of it would be met by a royalty levied on the tonnages already treated; the remainder would be amortized by the collection of royalty for a period of years long enough to permit the purchase to be redeemed, with current interest on the capital involved. Thus in five or ten years the industry would be relieved from the burden of litigation, and the greater incubus of inquisition and interference by the patent-exploiting agency, while the present litigants would find a reasonable solution of their troubles. In order to lift the settlement above a merely commercial and litigious level he suggested that the royalty, to be levied until the cost of purchase had been redeemed, include one cent per ton for the purpose of endowing a research fund, and the establishment of a central laboratory for progressive experimentation in flotation. Mr. Cook rose to thank the Congress for its

courtesy to him and to his associates. The meeting closed by the reading by Mr. Philip Argall of a paper on recent improvements in the treatment of ores by flotation. The contentious phase of the meeting was over and it remained only for the directors of the American Mining Congress to take action on Mr. Rickard's suggestion. This, we understand, was done in due course, the new president, Mr. W. J. Loring, being authorized to nominate a committee for the purpose.

Curtis H. Lindley

The death of Judge Lindley is more than a personal loss to his many friends, it marks the close of a career of great public usefulness. The Bar Association of San Francisco has expressed its respect for him as a lawyer. The president of that Association stated: "In his passing the Nation lost one of its most patriotic citizens, the State of California one of its most useful sons, the city of San Francisco one of its most trusted advisers in matters of great public concern, and this organization one of its hardest workers and its brightest ornaments." On the front page of his treatise on 'The American Law Relating to Mines and Mineral Lands' Judge Lindley quoted Bacon's admonition: "I hold every man a debtor to his profession; from the which, as men of course do seek to receive countenance and profit, so ought they of duty to endeavor themselves, by way of amends, to be a help and ornament thereto." He lived up to this precept; most assuredly he proved himself a help to his colleagues and an ornament to the profession itself. His treatise, usually known as 'Lindley on Mines', will remain an enduring monument to his industry, intelligence, and intellectual power. The first edition was published in 1897, and the second in 1903. The earthquake-fire of 1906 destroyed the plates of the second edition and the much more valuable notes already gathered for the publication of a third edition. It was a hard blow to our friend, but his courage rose superior to adverse circumstances and he proceeded indomitably to re-assemble the material for the third edition, which appeared in 1914. He was president of the San Francisco Bar Association for four years, president of the California Bar Association for two years, director of the Panama-Pacific Exposition of 1915, and a Park Commissioner; he was always ready to give the benefit of his advice in public matters and he was constantly consulted privately on affairs of great moment. In 1917 he became legal adviser to the Food Administration and drafted the bill creating the U. S. Grain Corporation. He assisted Mr. Hoover with his characteristic loyalty and sincerity, working so hard during the hot summer at Washington that he returned home an invalid. From this illness he never quite recovered; he was as truly a casualty of the War as if he had advanced with our troops in the Argonne; he was a faithful soldier and answered the call of duty as truly as if he had fought in the trenches, and with scarcely less danger to his life. On his return to Washington, after an absence of a year, he was crippled by ill health and yet would not abate his devotion to pro-

fessional duties. He continued to engage in sundry important litigations, the two latest mining suits in which he participated as senior counsel being the Bingham and Oatman cases. It gratified him greatly to win the former, for he had become impressed by the apparently fortuitous character of judicial opinions. He had just finished his part in the Oatman case, a cross-examination of the principal expert on the other side, when he was stricken with an internal hemorrhage, an hour after returning from the court-room to the hotel at Kingman, Arizona. He died as he wished, in harness. To mining engineers he was known as the most distinguished of the lawyers engaged in unraveling the complexities created by the effort to reconcile the apex law with geologic structure; in 1917 he was retained as an adviser in a famous British suit arising out of an apex litigation in Rhodesia; he was counsel for a number of important mining companies, among which we may mention the Bunker Hill, Alaska Treadwell, Alaska Juneau, Kennedy, Argonaut, North Star, Nevada Consolidated, and Inspiration. To others it has been permitted to achieve distinction in the law; Judge Lindley won a finer fame and a rarer record as a good citizen. In a republic, that is the supreme achievement. In days when cheap politicians slapped their chests and proclaimed themselves American, it was a relief, and is now a stimulating memory, to think of the Judge as the exponent of the American ideal of unremitting industry, undeviating integrity, alert intelligence, and devoted public service.

Electrolytic Zinc

Those who have tried to obtain trustworthy information concerning the technology of the electrolytic method of extracting zinc from its ores will have discovered to their chagrin that the superintendent or manager is usually quite willing to talk about his roasting and leaching processes, about his cathodes and his anodes, but when questions are asked concerning the purification of the electrolyte and the means employed for correcting the fouling of that metallurgical medium, he becomes evasive if not silent; in short, it is almost impossible to obtain detailed information concerning the critical part of the refining process. Therefore we take especial pleasure in publishing a comprehensive article on the subject by Mr. Herbert R. Hanley, who has been directing metallurgical operations, and the research incidental thereto, at the Bully Hill smelter in Shasta county, California. He describes the technique of the process whereby zinc is obtained electrolytically from ores and from smelter by-products. The successful application of electrolysis to the precipitation of zinc from a sulphuric-acid solution on a large scale is comparatively new, and, while much has been written regarding special features of the operation and numerous plants have been described in a general way, there was need of a comprehensive discussion of the problems that are presented and the methods by which difficulties may be overcome, such as Mr. Hanley gives our readers. He speaks with the confidence of one who has actually applied his technical skill to commercial

operations and his conclusions therefore may be accepted as authoritative, at least in the light of our present knowledge; it is imprudent, of course, to imply that any metallurgical process has been perfected. The recovery of zinc from a sulphide ore includes a series of preliminary operations each of which has a direct bearing on successful electrolysis. These are roasting, leaching, filtering, purification, and a second filtration just before the electrolyte enters the cells. The best roasting is accomplished when the zinc sulphate in the calcine is just sufficient to balance the acid-losses in the subsequent steps of the process, provided, of course, that there is produced a maximum amount of zinc soluble in acid. The technique of efficient roasting is discussed briefly. Leaching is done in a Pachuca vat. Cyanide operators might be inclined to take exception to the practice of calling this operation leaching; leaching rather implies percolation, whereas this process is one of agitation and filtration entirely analogous from a mechanical standpoint to the slime-treatment of gold and silver ores, except that the time required is short. Some of the contaminating compounds of iron and antimony are precipitated at this stage of the process by the addition of sundry oxidizing reagents. The first filtration is commonly done by means of a continuous vacuum-filter; silica, alumina, and some salts of iron, if present, retard the filtering and it is accordingly desirable to remove them as completely as possible in the leaching process, which, if properly regulated, does this satisfactorily. The next step, the purification of the solution, is the critical phase of the whole process. It is easy to precipitate zinc from a solution of nearly pure zinc sulphate by means of an electric current; but exceedingly small amounts of contaminating salts of copper, cadmium, and some other metals can spoil the result. Not only do they produce a spongy impure deposit on the cathodes, but they promote the re-solution of the deposited zinc, and may reduce the current efficiency to a prohibitive extent. Mr. Hanley goes into detail regarding this vexing problem and describes the chemical precipitation with zinc-dust as the standard method used at present. An electrolytic precipitation is technically possible, but the expense of erecting and operating the necessary equipment would not be justified under ordinary conditions. Purification is done by agitating the filtrate with zinc-dust in a Pachuca vat, while a pressure-filter serves to remove the small quantity of precipitate formed, leaving the neutral filtrate ready for the electrolytic cells. The regulation of current density, acidity, temperature, and electromotive force has been the subject of considerable research, the results of which are shown in a series of eleven typical curves that indicate clearly the effect of varying the different factors. We believe that Mr. Hanley's article will be of value to the engineer who must have a general knowledge of the electrolytic metallurgy of zinc, no less than to the metallurgist who is engaged in the operation of an electrolytic plant. It is a rare combination of practical and technical information, presented with care and precision.

DISCUSSION

The Belmont Shawmut Mill

The Editor:

Sir—In your issue of November 6 appears an interesting article on the operation of the mill of the Belmont Shawmut Mining Co., by A. B. Parsons. In the article several points are brought out that especially appeal to the engineer, perhaps on account of the difficulty of explaining the why's and wherefore's: First, the statement that the pebble-consumption was 1.3 lb. per ton of ore when the pebble-load was maintained at a point 10 in. below the centre of the tube, and the pebble consumption was only 0.3 lb. per ton of ore. This wide difference in pebble wear is unusual and the only plausible explanation is that the grinding capacity of the tube-mill, when charged with pebbles to the centre line, was too great for the feed introduced, the pulp circulating through the mill not being sufficient to properly cushion the pebbles, and thereby causing an undue contact of pebble against pebble.

A second point brought out was the importance of using sodium sulphide in the flotation-circuit; that the use of this reagent might serve to improve the grade of the flotation-concentrate by deflocculating the gangue is apparent, but just why the recoveries should also show marked improvement is more difficult of explanation because gold when associated with sulphide or when free and liberated from the gangue in a fine state of division usually yields itself readily to the ordinary flotative reagents.

Thirdly, the statement is made that mixing the fine raw flotation-concentrate with granular roasted concentrate has three important results; first the cyanide consumption is reduced, secondly, the recovery on the roasted product is slightly improved and, thirdly, that an increase of over 30% is effected in the recovery on the raw flotation-concentrate as compared with the recoveries made when treating the calcined and flotation-concentrate separately. The slightly improved recovery on the calcined concentrate when agitated with the fine flotation-concentrate may be explained by a lesser tendency of the combined product to stratify and becoming of too great a density in the lower part of the agitator for efficient dissolution of the precious metal. The great improvement in the extraction on the raw flotation-concentrate is more difficult of satisfactory explanation. Mr. Parsons mentions that before putting a fresh charge into the agitator an excess of ferrous sulphate is used to kill all free cyanide. It is possible that this and other similar soluble salts present in the calcined ore, alone or com-

bined with the scouring effect of agitating the coarser and finer material together, may have a tendency to free the raw concentrate from adhering oil-films, which would make the raw concentrate amenable to the action of cyanide solution. The rejection of oil from the circuit in the agitator-overflow would normally reduce the consumption of cyanide. It may also be that insufficient oxygen is taken into the pulp when agitating the raw flotation-concentrate alone. Mixing the two products, one being reducing and the other oxidizing, may set up an electro-chemical action that would accelerate the solution of the gold. The calcined product is delivered to the agitator at a temperature much above that of the raw concentrate. The temperature of the combined product would therefore be considerably above that of the flotation-concentrate drawn from the thickener. This change in temperature would no doubt result in improved recovery, but would hardly account for the full increase in extraction.

HENRY HANSON.

San Francisco, November 18.

The Rod-Mill

The Editor:

Sir—In a recent issue you mentioned the possibility of an improved rod-mill that might supercede the ball and tube-mills of the present day. You gave no details, and as our company, the Mineral Creek Copper Co., with mines in the Cascade mountains, within three hours ride from here, has installed such a mill which is doing excellent work, it may be of interest to your readers to know something about it.

It was patented four or five years ago and is a balanced-rod grinding-mill made at Tacoma, Washington, at Provo, Utah, and at Vancouver, B. C. It occupies a floor space of six by eight feet and is six feet high, set in a dust and water-tight case so that it can be operated wet or dry without any inconvenience to the workmen. There are two bearings outside this case easy to oil and get at. The main shaft is 7 ft. 6 in. long and 4½ in. diameter. There are two heavy steel castings keyed near the centre of the shaft, two feet apart and having circular openings 60° apart, 16 in. diameter, in which are placed 25 to 40 1 and 1½-in. rods four feet long. The entire lot of rods weighs from 2½ to 3½ tons. The circles are 4 or 5 in. wide and 1 and 1½ in. thick, which form tracks or rings for the rods to roll and tumble in as the mill revolves.

The construction is such that the mill is nearly balanced and requires only two horse-power to operate.

Between each set of rods is a 6-in. strip of $\frac{3}{8}$ -in. boiler-plate extending from end to end of the mill, which acts like elevator buckets to carry the overside up and feed it through the rods. There are twelve sets of screens 8 in. by $3\frac{1}{2}$ ft. and as soon as the material is crushed to size it leaves the mill.

We run the mill at a speed of 25 r.p.m. and have 28 ft. of 40-mesh steel battery-screen in use. We can easily mill from 2 to 3 tons per hour from the crushers which are set to $\frac{3}{8}$ -in. mill-feed. There is little wear on the rods, screen, or mill, and it makes an exceedingly simple construction, as it avoids the use of elevators, conveyors, screens, classifiers, de-waterers, and thickeners.

R. L. PARKER.

Tacoma, Washington, November 17.

The Ore Deposits of Mexico

The Editor:

Sir—Having had occasion to review a mining report on a mine in Zacualpan district, Mexico, in which reference was made to the articles on the 'Ore Deposits of Mexico' by S. J. Lewis that you published recently, I searched my files and read with much profit the article describing the above named district. Finding it unusually instructive I was led to go back and read *all* of the contributions in sequence.

My purpose in this communication is to ask if you will not, in future, by short editorial paragraph, draw attention of your readers to matter of this kind, particularly where it appears as in this case, over a period of eight months, interrupted between numbers II and III by fully three months.

Articles as deserving of attention as Mr. Lewis's are worthy of more than one editorial reference, and busy men among your subscribers will thank you for a reminder which will lead to picking up some desirable reading matter that otherwise may be overlooked.

At the present time Mexican mining is surely coming into its own, unless all signs fail, and stimulation on your part to further contributions from those who are competent to write about Mexico is one of your duties to your readers.

F. L. SIZER.

San Francisco, November 12.

The Price of Gold

The Editor:

Sir—In the 'Press' of October 30, Mr. W. B. Chomley has a note on 'The Price of Gold' in which he fails to note the dual features of gold, namely, price and value.

Price is the mask which hides the value. To illustrate, I quote from your editorial column of March 20:

"Evidence introduced in a London police court against seven persons, one of whom is described as a gold miner, shows that 110,000 sovereigns were withdrawn from the Bank of England and melted into bullion, *which was then sold at a premium.*"

These persons didn't melt up the sovereigns as a metallurgical experiment, nor was the destruction of King George's likeness only a matter of vandalism. These persons were after a profit. They knew what many close students of the subject know, that gold has a price and also a value, the price being stamped upon coins as a mask to hide the value. The culprits in this case merely melted the mask and exposed the value.

The price of gold today is \$20.67 per ounce; the value is more nearly \$45 per ounce.

P. A. ROBBINS.

San Francisco, November 6.

[The British sovereign, in London, is worth more dead than alive, that is, its bullion value is greater than its coinage value. This is not true of an American gold-piece, which remains at a price proportionate to the amount of bullion in it, at \$20.67 per ounce. The British paper sovereign is at a discount commensurate with the premium on gold, in Great Britain. The U. S. \$5 paper bill remains at parity.—EDITOR.]

Mr. Hoover's Biography

The Editor:

Sir—A few lines in reply to Mr. Field's letter in your issue of November 13. Apart from my error in saying that there was no office operated by Bewick, Moreing & Co. at Coolgardie, I do not feel inclined to retract what I wrote in your issue of August 28. Mr. Field spoke generally in his biography in the 'Sunset Magazine'; now he specifies where the single-jack drilling method was adopted in Western Australia. I have sent copies of the 'Sunset' for July to friends in Australia, and they considered the matter in the same light as myself. An Australian in British Columbia first drew my attention to the article discussed, so apparently I am not the only one who regarded the matter as a slight on Australian methods. What riles me is such passages as: "A man over thirty can't stand Australian climate and living conditions, they say, and it takes a man of seventy-five to handle their problems down there." . . . "Mining there was in the kindergarten stage of sixty years ago in California. It fairly made an American engineer weep." . . . "They refused to use the new tools; they flung them into the machinery of the stamp-mills . . ."

I wish it to be remembered that in this discussion I am not trying to depreciate Mr. Hoover in any way, far from it; I simply want Australians to get fair play. And as I was one of the very few metallurgists that wrote on Australian practice from 1906 to 1913, as you will confirm, I feel it a duty to continue to do so in America.

MAX VON BERNEWITZ.

New York, November 17.

DURING THE WAR 83% of the platinum consumed in this country was used in essential industries (chemical, electrical, and dental), but in 1919 only 40% was used, and the quantity used for jewelry increased from 12 to 56%. The remaining small percentage was divided among several minor uses.

Electrolytic Zinc Methods

By Herbert R. Hanley

INTRODUCTION. The development of processes that have had practical application in the production of electrolytic zinc have received a great stimulus during the past five years. The subject had received considerable attention two or three decades ago by many investigators, and most processes evolved at this early date were based upon principles which are followed, to a considerable extent, in current practice. The study of these principles has given a better understanding of them and has led to the formulation of a few new ones and also to the deduction of a few corollaries. The development of methods that have economic application, however, has been the greatest factor in the growth of the industry.

The technique of electrolytic zinc has received considerable attention in the literature of the profession during the past few years, and anyone attempting to write on the subject is likely to indulge in considerable repetition, but to the extent that this appears necessary for illustration, I shall make no attempt to avoid it.

The economic electrolytic deposition of zinc from solution is an operation that must be performed in the electrolyte containing this metal as a sulphate, in the absence of certain other substances or with a limited amount of them. This is an essential fundamental condition. It is now generally recognized that the earlier processes for the production of electrolytic zinc did not have dependable and economic methods for the purification of the solution. There are many other factors of vital importance, but they are secondary to those involving purification, which if not effectual will cause a defeat of the purpose in hand. With this idea as a premise for the economic production of electrolytic zinc, the various steps of the work will now be considered.

The principal source of raw material is the zinc sulphide or oxidized zinc ores. A minor source at present, but which may become an important one, is represented by condensation products from smelters collected in bag-houses or by means of the Cottrell precipitator.

PREPARATION OF ZINC-SULPHIDE ORES, ROASTING. A better understanding of the conditions required in the roasting of zinc ores has led to the production of a calcine that has a smaller percentage of zinc insoluble in dilute sulphuric acid than was formerly the case. The extent to which this insoluble form of zinc is present in a calcine varies with the composition of the ore and the condition of the roast.

In the purification department there are certain losses of solution containing zinc. Incidental to these losses there is also a loss of potential sulphuric acid represented by the sulphate radical of the zinc-sulphate solution. To the extent this potential sulphuric acid is lost, new acid must be introduced, either in the form of purchased acid

or by the formation of potential acid in the calcine, which is represented by the formation of zinc sulphate. All zinc plants strive to obtain a balanced system in regard to sulphuric acid; that is, efforts are made to form, by sulphate roasting, sufficient sulphate of zinc to balance the acid losses taking place in other departments.

There are several factors governing the amount of zinc sulphate formed in the roasting-furnace. These factors include the quantity of air that can come in contact with the particles of ore, the percentage of iron in the ore, the character of the iron-sulphide crystallization, and the temperature at which the operation is performed. C. A. Hansen has done some valuable work on the roasting of ores and has made important contributions to the literature on the subject.* He has pointed out the rôle played by iron in the formation of sulphate, and particularly the effect of isomorphous crystallization of iron and zinc, as well as many other important factors. This subject embraces a field too large for discussion in this article.

The subject of rabbling is one that operators regard with great importance because it is responsible for the oxidation of the ore particles. The roasting of a given type of ore containing approximately 25% zinc, 15% iron, and an amount of sulphur that would indicate the absence of isomorphic crystallization of these two metals, when carried out under uniform conditions except for the degree of rabbling, will yield a calcine with a wide variation in the proportion of zinc sulphate formed. An increase of rabbling in the zone where the first atom of sulphur is being volatilized, including the subsequent area where there is considerable exothermic action, in a measure minimizes the amount of acid-insoluble zinc compounds. This method of rabbling saves a certain amount of zinc that can be converted into soluble oxide and sulphate where conditions are favorable for their formation. The admission of a large amount of air is directly reflected in the low sulphur di-oxide content of the roaster gases, and this condition is necessary for the formation of zinc sulphate.

The calcine produced from ores containing above 16% lead usually has a lower percentage of total soluble zinc. This condition may be due to the influence of the lead or to the crystalline condition of the iron, or a combination of both.

SMELTER-FUME. The condensation products from bag-houses or Cottrell precipitators, when operated in conjunction with blast-furnaces treating copper or lead ores, frequently have a high zinc content. If this product, which may be termed 'fume', contains some of the more valuable metals that are recoverable as by-products, then the treatment of this oxidized material for the recovery

*Bulletin A. I. M. E., August 1919.

of zinc electrolytically becomes an important matter.

Bag-houses in general produce a fume containing a larger amount of arsenic than is usually present in the zinc ores offered for treatment in an electrolytic zinc plant. The treatment of the fume in this kind of plant involves first the separation of the arsenic. The selection or development of methods to carry out this step will be influenced by the oxidation state of the arsenic. If this element is uncombined with other metallic bases and is in the lower or trivalent state of oxidation, it can be volatilized by heat alone. If combined with other bases, however, then more involved methods must be employed for separating it, inasmuch as simple heat-treatment will not then be found effective.

In this article the fire method only will be considered for the separation of arsenic from the fume.

It is well known that if sulphuric acid is mixed with an arsenical zinc fume in proper proportion to unite with the bases that are in combination with the arsenic as arsenites and arsenates, there is a volatilization of a certain amount of the arsenic during the roasting of this mixture, and the zinc is converted into sulphate. The amount of sulphuric acid required for such work will vary with different kinds of fume, but it will be represented usually by a quantity calculated to combine with the valuable metallic bases that can enter into solution. In this case zinc is desired in solution, and the sulphuric acid is mixed with the fume in an amount corresponding to its equivalent combining weight with this metallic base. A slight excess of 10 to 15% sulphuric acid is usually added to make up for acid losses incurred by its combination with other inherent bases.

The mixing of the fume with dilute acid is an operation that is by no means simple. There is a tendency to form cement-like solids during the mixing of these substances, and this troublesome condition must be largely overcome to conduct the operation economically.

ROASTING OF THE ACID-TREATED FUME. There is a progressive conversion of iron compounds to sulphate as the roasting proceeds during the first half of this operation, after which there is a gradual oxidation of the ferrous sulphate to ferric oxide. The copper compound is converted progressively into sulphate throughout the entire roasting period, and becomes maximum at the time of discharge. There is only a slow volatilization of the water-soluble arsenic during the first quarter of the period, then it becomes eliminated quite rapidly. Table I shows the changes taking place during roasting.

The elevation of the temperature is made progressively and care must be taken to avoid sintering near the zone of heat introduction. Low temperatures are maintained during the roast to avoid crusts, which would be readily formed if abnormal rises of temperature were permitted. The initial temperature of 330°C. is present on the second hearth and approximately 510°C. on the seventh or lowest hearth. When the seventh hearth is cooler than the sixth, there is an increase in the water-soluble iron noted on the former; in other words, there is a consistent reduction of iron from the water-insoluble form on the

sixth to a water-soluble condition on the seventh hearth when the temperature is as above stated. This is overcome by maintaining the two lower hearths at approximately the same temperature.

LEACHING. The treatment of the calcined zinc-bearing material, whether obtained from ore or as a bag-house product, is an operation that is devised to meet the requirement of separating the soluble zinc compounds from the solids. The method of performing the operation will vary with the character of the calcine.

The so-called Pachuca tanks (or Brown agitators) are generally used for this purpose; they are more simple, they are of larger capacity, and require less repairs than other vats of the kind. Under certain conditions agitators of the paddle type are indicated; these treat a smaller quantity of material and require more repairs.

The length of the leaching operation is governed by the rate of solubility of the zinc in the solution. If this rate is slow, then a long leaching time is implied. In some plants this is done by more or less continuous leaching in a series of vats, thus giving a prolonged contact between the calcine and the solution. The complete leaching of water-soluble zinc salts from a calcine is accomplished in a few minutes, and any prolonged period of leaching does not accomplish further solution.

The zinc that has gone into solution from the calcine represents the percentage solubility referred to the total zinc and should not be termed 'recovery', because this term, when used in an unqualified manner, signifies the amount of metal produced in marketable form referred to the total zinc in the raw material entering the plant.

The leaching of calcined ores is performed by agitation in an acid electrolyte obtained as an effluent from the electrolytic zinc cells. The leaching of the acid roast fume calcine is performed by adding it to water or a neutral weak solution, obtained as wash-water, during suitable agitation provided by Pachuca or paddles. The zinc content of the primary solution obtained from the leaching is usually regulated to approximately 90 to 100 grammes of zinc per litre, this figure, however, is subject to variation, depending upon the rate at which the residue settles, the filterability, and the degree of solution purification required.

LEACHING OF RAW ARSENICAL ZINC FUME. The raw fume contains elements as oxides or oxygen-carrying compounds, which are, to a large extent, soluble in dilute sulphuric acid. The leaching of this material usually requires a different procedure common to general practice.

The fume that has been collected and stored as a mud contains arsenates of the metal due to the oxidation of the original arsenites previously mentioned. The principal arsenical compounds present during the leaching of this class of fume are the arsenate and the arsenite of zinc. The arsenate becomes a gelatinous translucent precipitate when the solution containing it is neutralized. This compound is difficult to filter and practically impossible to wash. A fume containing 2 or 3% arsenic as arsenate forms such a thick gelatinous mass upon neutralization in the leaching-vat that the agitation is

practically annulled and the tank content cannot be discharged through a pipe-line. Arsenites do not cause this condition.

In leaching the former class of fume, with dilute sulphuric acid, care must be exercised to the end that the pulp does not become neutral during this operation. Under certain conditions it becomes necessary to limit the amount of acid used for leaching because of an insufficient plant production of this reagent to balance the acid system. In this case sulphur di-oxide gas, 6 to 10% by volume, may be used to balance the acid deficiency. To carry out this method of leaching, the fume is slimed, delivered to an agitating-vat containing neutral solution, and the sulphurous gas delivered to cause a solution of the excess portion of the acid-consuming constituents. This procedure permits the completion of the leaching with the reduced available supply of sulphuric acid.

Melted aluminum		0.003 "

During this part of the leaching there is sufficient reduction of arsenate to arsenite to permit the addition of sulphuric acid to the pulp without the arsenate gelatinization of the mass in the vat. Without this incomplete reduction to arsenite, however, the addition of acid to the pulp induces an objectionable semi-solid condition of the pulp. It will be understood that the mere suspension of the fume in neutral solution does not cause gelatinization because no arsenates are dissolved until acid has been added.

EFFECTIVENESS OF SO₂ IN ZINC-SULPHATE SOLUTION. The solubilities of pure sulphur di-oxide in the zinc-sulphate solution at various temperatures are as follows (see Table II) :

If the preliminary leaching is made by a 7% SO₂ gas,

Fig. 1. General Washing Curve.

Fig. 2. Curve Showing Solubility of SO₂ in Zinc-Sulphate Solution Interpolated Beyond A. and B.

then the SO₂ present in the gas mixture can only exert 7% of the pressure, which permits a given volume of pure SO₂ being dissolved in one volume of solution at a given temperature. If the temperature of the solution absorbing the gas is 60°C., it will be seen, in Table II, that 5.4 volumes of SO₂ are dissolved in one volume of zinc-sulphate solution, if 100% SO₂ gas is used. The 7% SO₂ gas $\frac{7 \times 5.4}{100} = 0.378$ volume.

This is equivalent to 100 cc. solution dissolving 0.0378 litre SO₂ and the weight of this gas at 60°C. is $2.32 \times 0.0378 = 0.0876$ gm. If the weight of 100 cc. zinc-sulphate solution is 122 gm., the percentage of SO₂ in the solution amounts to $\frac{0.0876 \times 100}{0.122} = 0.071$ of 1%, or 0.87 gm. SO₂ per litre of solution. It will thus be seen that 0.071 or 0.87 gm. of SO₂ per litre is approximately the maximum of absorption when using 7% of SO₂ gas.

While this percentage of SO₂ dissolved is low, the re-

sults are materially augmented in the presence of sulphites or bi-sulphites of the heavier metals. Thus when SO_2 is combined with CaO or ZnO , it can be present to the extent of several percentages. In such cases the solution acts first as a carrier between the SO_2 and the heavy metallic bases, and second as a better solvent for the zinc salts by virtue of its newly acquired property.

Inasmuch as there are arsenates present in the pulp in suspension, there is a fairly rapid oxidation of the SO_2 to H_2SO_4 , which dissolves more zinc and arsenic from the fume, and the continual presence of SO_2 prevents arsenates being formed in the solution. A solution of zinc as sulphite can be quite rapidly changed into the sulphate by the means of air agitation.

FILTRATION. The great irregularity in the filtering rates for different classes of materials in connection with the degree of filter-cake washing required and the disposition of the residual solids make the selection of a filter best suited for the work a matter of considerable circumspection.

Filtration of suspensions of calcine-residue is always performed where economically possible, on thickened pulp by a continuous vacuum type of filter. Some kinds of fume, however, do not settle well; in fact, under certain conditions no perceptible settlement occurs with this class of material. The filtration is usually performed by delivering the material in an unthickened condition to a pressure type of filter, whereby higher pressures can be applied than can be obtained in vacuum-filter. It is true generally that a suspension of solids that cannot be thickened has a slow filtering rate, and if this unthickened pulp were delivered to a continuous-vacuum filter, the cake formed would be extremely thin, and as such cannot be efficiently washed nor effectively discharged from the filter-cloth.

To maintain a workable condition of the cloth in a mechanical filter it is quite important that the cake formed be of sufficient thickness to possess a coherent property, so that it can be dislodged in mass from the cloth by air-pressure from within. The imprint of the cloth-fabric is present on the inner face of the cake when removed properly. The scrapers employed to remove the cake after it has been separated from the filter-cloth by air-pressure, cannot be used effectively to separate the cake from the cloth, inasmuch as this action forces the fine solid into the pores of the cloth, resulting in premature clogging of the filtering medium.

For obvious reasons, the washing of filter-cakes to remove soluble zinc salts cannot be done with perfect replacement by the wash-water. Such an operation would imply only the use of a volume of wash-water equal to the volume of the liquid entrained in the cake to accomplish the desired end. Perfect replacement, however, only occurs during the first part of the washing cycle, and soon becomes inoperative owing to the diffusion of weaker solution into the stronger liquid in the cake. The amount of soluble salt removed per unit-volume of wash-water then becomes approximately uniform for a short time, after the soluble salts are greatly reduced in the

cake, then a relatively less amount of these salts is removed per unit-volume of wash-water.

By plotting the volumes of the wash-water used per unit of zinc dilution along the abscissa, and the zinc contents of the filter-effluents along the ordinate, the following curve results; a short horizontal line representing perfect replacement, then this is bent to an inclined position coinciding with diffusion, and later, after a certain amount of soluble salts has been removed, the inclined portion is bent back somewhat, again approaching the horizontal, coinciding with that part of the wash which requires an enormous quantity of wash-water to remove a small amount of soluble zinc. This is shown diagrammatically in Fig. 1. The extent of filter-cake washing in practice is limited to an amount which will cause only permissible dilution of solution, as there is no material concentration of liquid in other parts of the plant.

There are many substances that exert a retarding influence on the rate of filtration and on the rate of effective washing. It is the physical condition of these substances rather than the substances themselves that is responsible for this influence. Generally speaking, colloidal matter in the mixtures to be filtered exerts this retarding influence. It is known that most of the elements can be caused to exist in the colloidal state, in which condition the extremely minute particles of the solids in suspension in the liquid remain apparently in perfect equilibrium with reference to their positions in the liquid; the influence of gravity tending to cause the suspended particles to settle is less than the forces which maintain the perfect suspension. These forces also exert an effective resistance to the separation of the suspended solids from the liquid when filtration is attempted.

Among the principal substances that have a retarding influence on filtration and the washing of cakes are silica, ferrous and ferric iron, alumina, and the arsenates of metals. The problem of overcoming the effects of these or similar substances is one that must receive first attention.

The leaching of calcined ore producing a solution which is slightly acid, presents a mixture that can be easily filtered and washed. The precipitation of silica and iron from this filtrate, obtained as above, may be accomplished by the addition of a base such as powdered lime-rock or calcined ore in the presence of an oxidizing influence. When this is performed by the addition of calcined ore, the gelatinous silica and flocculent iron compound become mixed with the incompletely leached residue of this calcine. The filtration of these solids from the solution, which is now neutral, is done fairly easily but the solids are quite voluminous and flocculent, and by virtue of this property, a large quantity of solution is entrained in the filter-cake, from which it is not only difficult to remove by washing, but the volume of wash solution resulting from this wash would be in excess of that which could be economically used in the solution system.

This filter-cake obtained from the filtration of the solution that has been treated a second time with calcine con-

taining a large amount of entrained water-soluble zinc together with the residual unleached zinc oxide of the residue, in addition to the gelatinous silica and flocculent iron compound, is given a heat-treatment at 150°C. to

substances that have the deleterious effect of entraining soluble zinc salts in filter-cakes, and in all cases these methods have to be adapted to the particular class of ore and the local conditions. Some of them do not involve

dehydrate the silica and iron. This treatment renders these two substances insoluble in dilute sulphuric acid, which is used to dissolve the zinc compounds following the dehydrating operation.

There are other effective methods for separating the

heat-treatment for the separation of silica and iron from the soluble zinc.

The ores sent to the electrolytic zinc plant for treatment seldom contain soluble arsenic in excess of one-hundredth of the soluble zinc. The amount of arsenic

indicated by this ratio is too small to exert a serious effect on filtration or zinc recovery regardless of the form in which this element is present.

There are bag-house condensation products, however, that contain soluble arsenic to the extent of a quarter of the soluble zinc. When this class of raw fume is leached direct with dilute sulphuric acid, the treatment of this arsenical zinc solution presents a problem more complex than that presented in an electrolytic zinc plant treating ores. The arsenites of the metals in solution form a granular precipitate upon neutralization and therefore offer no serious filtration nor initial zinc-recovery problem. The arsenates, however, form a translucent jelly-like mass upon neutralization and would not only defeat the economic filtration but would change the entire contents of the leaching-vat to a gelatinous mass that would not flow through a pipe-line. Consequently, in the presence of considerable arsenate, the solution obtained in the leach must not become neutral and is filtered in the slightly acid condition such as 6 to 8 gm. H_2SO_4 per litre.

REMOVAL OF IRON FROM ZINC-SULPHATE SOLUTION. Some mention was made of the precipitation of iron in the foregoing paragraphs, but it was done only for the consideration of the inherent effect of the iron precipitate on the filtration of the residue. The precipitation of iron from zinc solutions will now be considered in a chemical sense.

It is a matter of common knowledge that iron cannot be completely precipitated by a base, such as zinc oxide, hydrated lime, or lime-rock, unless it is in the ferric state of oxidation. Practically all the soluble iron contained in solution obtained by leaching a roasted zinc-concentrate or fume is in the ferrous condition. When this solution is treated by a base without oxidation, the iron compound formed is not completely insoluble, and during subsequent filtering operations, part of this compound passes through the filtering medium, and part remains with the cake. The effective removal of the iron from the solution is therefore defeated by this treatment.

The oxidation of iron in neutral solution, when present in the usual amounts, namely, 0.1 to 3 gm. iron per litre, may be done economically by the use of oxidizing agents, such as manganese di-oxide, or other di-oxides when low in price, or by means of air agitation. The last is not effective if the solution is acid.

Manganese di-oxide is more rapid in its action than air agitation. The latter alone can be made to do the work effectively if the air-bubbles are in a fine state of division; if those bubbles are large, the oxidation of the iron is extremely slow, and therefore the operation is not performed economically.

Proper conditions for agitation by air are obtained by forcing compressed air into felt-covered boxes set above the bottom of the vat containing the solution to be treated. The vat used for this purpose has a conical bottom and is fitted with a Pachuca air-lift, to keep the entire contents in perfect suspension. The felt boxes set above the bottom of the vat suffer less interference from solid matter than would be the case if placed on the bottom.

The oxidation of iron by air is very greatly retarded if the solution has not been separated from the leached residue. This metal, if present in large amount, therefore, should be oxidized in solutions that have been filtered from the main leached residue, that is, if air alone is used for such oxidation.

The precipitation of iron is accomplished by the addition of the most economical base in presence of an oxidizing influence. The bases generally used are powdered lime-rock or calcine containing zinc oxide. The lime, falling to the bottom of the vat, is continuously elevated to the surface of the liquid by means of the Pachuca, which ensures effective circulation of the solution into the active oxidation zone caused by the passage of air through the felt boxes.

The complete precipitation of iron by powdered lime-rock in presence of minute air-bubbles is more economical when applied to a solution that is free from copper and cadmium. The precipitation of the iron following the removal of copper and cadmium from solution, implies a condition of operation seldom encountered in the treatment of roasted ore. The acid leaching of the latter yields a solution that must be subsequently neutralized by calcine, or by calcine in conjunction with a small amount of powdered lime-rock. This neutralization starts the precipitation of the iron, and having started, it should be completed at this stage of the work. Therefore in the treatment of ores, the iron is generally removed prior to copper and cadmium.

The water-leaching of fume that has been given an acid roast yields a solution of sulphates that is practically neutral with all the soluble metals in equilibrium, and therefore the order of removing the impurities from solution is guided by expedience. Under this condition the iron can be precipitated most advantageously by a non-zinky base, such as powdered lime-rock. The precipitation of iron with this reagent, instead of a zinc compound, renders the subsequent work simple, in that there is no material amount of residual zinc to recover. If a calcine containing zinc oxide were used for this purpose then an additional step of recovering the unleached oxide would have to be provided.

The precipitation of the iron in presence of two to six grammes of cadmium per litre in solution is accomplished slowly. The presence of cadmium in the above proportion retards the action between the powdered lime-rock and the solution to a considerable degree, necessitating the addition of a large amount of this reagent and prolonged air agitation to cause the precipitation of the iron. The operation under these conditions produces a large weight of precipitate, which carries a proportionally larger amount of entrained zinc as hydrate and sulphate.

Cadmium sulphate is not only irresponsive to powdered lime-rock, but it exerts an influence preventing the action of this reagent on other salts in solution; if it be present to the extent of 20 grammes per litre the action of the lime-rock as a purifier of the solution is nullified.

Copper does not have any marked effect on the precipitation of iron except to promote the consumption of a

Fig. 14. Curve Showing Current-Efficiencies for Solution Containing Small Amount of Zinc.

larger amount of the lime-rock used in precipitating a part of the copper, and thereby increasing the weight of precipitate and the incidental loss of zinc. The removal of soluble iron from a solution that is free from copper and cadmium is accomplished by the addition of a small amount of powdered lime-rock, in a short period of air agitation. For example, a solution containing two grammes of ferrous iron per litre in the presence of six grammes of copper and five grammes of cadmium per litre occasions the use of approximately 80 lb. of powdered lime-rock per 1000 gal. and requires about eight hours of agitation, whereas a solution of the same iron content and free from copper and cadmium will only require 10 to 16 pounds of the lime-rock per 1000 gal. of solution and require from one to two hours.

The area of felt to be used for producing minute air-bubbles will amount to 20 sq. ft. per 16,000 gal. of solution. The weight of the dry solid in the precipitate usually amounts to 1.7 times the weight of the lime-rock used.

It has been proved that iron can be precipitated in a zinc solution free from copper and cadmium by small-bubble agitation without the use of powdered lime-rock or any other base. Curves showing the rate of iron precipitation for these experiments are shown in Fig. 3. Four hundred gallons of solution were used for each experiment. Curve No. 1 shows the results obtained without the addition of powdered lime-rock until the ninth hour of agitation, when half-pound was added. This caused the complete precipitation of the iron. Curve No. 2 shows that 14½ hours of agitation with air removed the iron, without the addition of lime-rock. There is a certain amount of zinc precipitated along with the iron, and both metals as precipitated were in the form of basic sulphates. This fact has an important bearing on the removal of iron from solution and although it would be impracticable to carry this out on a large scale, under certain conditions this method of operation may be available in part.

It is to be understood that the phrase "complete precipitation of iron" will be liberally interpreted, as there is a trace of iron present in all metallurgical solutions subjected to treatment for its precipitation.

COPPER-CADMIUM PRECIPITATION. It is a matter of common knowledge that copper and cadmium are galvanically precipitated from solutions by means of metallic zinc. Zinc-dust, made by a blast of air through a stream of molten zinc, is the most satisfactory form of this metal for use in the precipitation of the above metals, under usual conditions. The method of application consists in circulating the impure solution and a proper quantity of zinc-dust through a Pachuca air-lift placed in a cone-bottomed tank. This simple method is quite effective, and causes a rapid precipitation of copper.

Cadmium, on the other hand, is not so rapidly precipitated and there is a slight re-solution of the compound precipitated. These facts make the complete removal of cadmium a difficult operation unless special precautions are taken. The difficulty varies with the

amount of cadmium present. The zinc ores that are usually treated in an electrolytic plant seldom contain more than a trace of cadmium, and therefore the problem of removing it from solution is a minor one, and no additional step in the process is necessary. Bag-house products, on the other hand, are likely to contain a notable quantity of this metal. The treatment of these products in an electrolytic plant is planned in order to avoid the difficulty, the discussion of which follows:

A slight re-solution of cadmium takes place when a mixture of the copper and cadmium precipitates remain in contact with the zinc solution from which they were precipitated. This re-solution also occurs during filtration of the precipitated metals, unless the filter-cloths have been washed free from solids collected during a previous cycle.

The immediate filtration of a purified solution containing precipitated metals in suspension occasionally gives a filtrate sufficiently low in cadmium to send to the electrolytic cells. This simple procedure cannot be depended upon to give consistent purity of solution because of the uncertainties inherent in any method dependent upon operations that are restricted to narrow limits. The solution containing three or four grammes of cadmium per litre is given two treatments with zinc; the first one precipitates practically all the cadmium, which is separated from the solution by filtration, while the second zinc treatment precipitates the re-dissolved metal from a solution that is nearly pure. The solution containing a small amount of cadmium in suspension from the second treatment is immediately pumped through a clarifying filter-press, the effluent flowing to the cell-room.

A comparison of the rates of precipitation of copper and cadmium is shown in Fig. 4. Copper is precipitated quite rapidly from the start; a retardation in the rate is observed as the metal approaches depletion. Cadmium is precipitated slowly at the start, then gains a rate nearly equal to the copper precipitation. The general results show that the cadmium lags behind the copper in this work.

SEPARATION OF COPPER AND CADMIUM FROM ZINC SOLUTIONS. Electrolytic removal of copper and cadmium from the zinc solution is not of commercial importance at the present time, but it may receive attention under changed conditions. In 1914 some work in this direction was done; the copper and cadmium were removed at a voltage that would not cause precipitation of the zinc.

The experimental work was performed in a cell containing two anodes and one cathode. The cathode was made of sheet-lead, 23 in. wide and 27½ in. long. The anode was of the multiple-pipe type, and consisted of a horizontal pipe from which fourteen half-inch lead pipes descended into the solution. The quarter-inch pipes form the active part of the anode, as well as provide uniform air agitation in the cell. A complete description of this anode will be found in my patent No. C 1,241,967 on electrolytic apparatus.

The great difficulty of this operation is to maintain sufficient conductivity of solution to avoid extreme low-

Fig. 15. Curves showing K.W.H. for Various Current Efficiencies and Voltage

current densities. The conductivity of a solution containing

Zinc	90 gm. per litre
Copper	5 " " "
Cadmium	0.5 " " "

increases rapidly from the start until approximately 50% of the copper is precipitated, when it falls with equal rapidity until about 90% of this metal is removed from solution; then there is only a very gradual reduction of the low conductivity of the solution until the copper is finally precipitated. Note: the cell was operated as an accumulating acid-cell, without feed or overflow. The curves shown in Fig. 5 represent the current-density with reference to time and copper. The copper deposit is coherent until it has been depleted, to 50 or 60%, when it becomes spongy and contains some copper oxide. The oxide is soluble in dilute sulphuric acid, which accounts for the vacillating action near the end of the electrolysis.

The expense involved in erecting and operating this type of plant would not be justified when compared with the more simple methods of copper-cadmium precipitation; the apparent lower cost of electric power compared with zinc-dust would be annulled by complicated operations.

ZINC ELECTROLYSIS. Considerable study has been given to the electrolytic deposition of zinc during the past seven years, and it has led to the recognition of sundry essential operating characteristics. Cathode zinc made from properly purified solution resists the attack of dilute sulphuric acid to a very great extent. This acid-resisting property of the deposited metal is one of the fundamental requisites, otherwise the economic application of electrolysis to zinc solutions would be defeated. After cathode zinc has been melted and solidified it becomes readily soluble in dilute sulphuric acid. Electrolytic zinc deposition is confined to solutions high in acid, namely, 50 to 90 gm. of H_2SO_4 per litre; therefore the acid-resisting property of the zinc is essential. If this were not the case this metallic deposit would be dissolved at a prohibitive rate.

A general idea of the corrosion of cathode zinc, melted cathode zinc (iron or graphite pots), rolled zinc, and rolled aluminum may be seen in Table IV.

CURRENT, VOLTAGE, TEMPERATURE. The drop in the electro-motive force (E. M. F.) of an electrolytic-zinc cell, for a current that is practically zero, is approximately 2.6 volts at the ordinary room temperature. The approximate average voltage for economic operation is 3.6. It will be seen then that about 72% of the E. M. F. is represented by electro-chemical resistance and 18% by ohmic resistance. With a given current-density, the acidity of the electrolyte has the greatest influence upon the voltage of a cell.

The temperature of the electrolyte has only a moderate influence upon the voltage. The rise of temperature in electrolytes that are nearly neutral will cause a much greater percentage reduction in the voltage than for highly acid solutions. The voltage, current, tempera-

ture, characteristics for electrolytes between neutrality and 101 gm. of acid per litre, from 36°C. to 73°C., and from zero to 100 amperes per square foot are shown on Fig. 6, 7, 8, 9, 10, and 11. Fig. 12 shows the influence of the acid upon the voltage for various temperatures at 25 amperes per square foot. Fig. 13 shows the influence of temperature upon the voltage for 25 amperes. The experimental work for the collection of these data was extended over sufficient time to ensure constant conditions in each test.

For regular operations the current density is usually controlled between 25 and 30 amperes per square foot, the acidity between the limits of 30 and 100 gm. per litre, the average voltage is usually 3.6, and the cell-electrolyte is cooled by water-pipes to 30 or 40°C. Unless cooling water-coils are placed in the cells the temperature will rise above 60°C., when the cathode zinc is energetically attacked by the acid electrolyte.

CURRENT-EFFICIENCY. In electrolytic zinc work the efficiency of the current is very close to the difference between the theoretical ampere yield and the losses sustained by chemical corrosion. The over-all current-efficiency in cell plants that operate on properly purified solution, the overflow of which contains about 20 gm. zinc per litre and 96 gm. acid per litre should be approximately 80%. The electrolyte becomes more corrosive to cathode zinc as the zinc content of the solution becomes less than 20 gm. per litre.

The curve shown in Fig. 14 represents the ampere efficiency in depositing zinc from attenuated zinc-sulphate solution under good conditions. There is a decided break in the efficiency when the zinc in solution is depleted below 10 gm. per litre, after which there is nearly a horizontal decrease in efficiency as the metallic content approaches exhaustion.

The solution containing 20 gm. Zn/L also contained 100 gm. H_2SO_4 /L, while the solution containing 5 gm. Zn/L contained 121 gm. H_2SO_4 /L. It is readily seen that operation much below 20 zinc/litre is not economical.

KILOWATT-HOURS. The curves shown in Fig. 15 may be useful in quickly determining the kilowatt-hours per ton of cathode without calculation. These curves cover the range of current-efficiency from 100% to 50% and at E. M. F. values between 3 and 5 volts. The lower set of curves show kw-hours per ton of cathode without reference to motor-generator efficiency. The middle set shows the kw-hours per ton including an 84% motor-generator efficiency. The upper set of curves shows the cost per ton of cathode for various power-rates (all line losses and transformer losses being excluded).

Example: assume voltage at 3.6, current-efficiency at 82, power-cost at 0.45 cent per kw-hour. The lower set of curves opposite 3.6 volts intersects the incline at 82% on 3200 kw-hour value. The middle set opposite 3.6 volts intersects the incline at 0.84×0.82 vertically above 3850 kw-hours. The vertical extended upward from 3850 cuts the incline cost-curves of 0.45 kw-hour at a point that, when extended over to the left margin of the paper, indicates \$17.30 per ton of cathode for power.

Milling Practice at the Benguet Consolidated Mine—I

Historic Notes and Development of Methods

By C. M. Eye and M. F. Dodd

The first milling of ores from this mine, situated in the Benguet district of the Philippine Islands, was in a small plant ordered in 1905, and placed in operation late in the following year. This, the first plant in the Islands to include cyanidation as a part of the treatment, consisted essentially of the following equipment: One 7 by 10-in. rock-breaker, one Hendy three-stamp individual mortar in a quadruple-discharge battery, with apron and table plates for outside amalgamation, one bucket-and-belt elevator, one upward-current inverted-pyramid type of wooden classifier (made on the ground), a Butters & Mein distributor, six Oregon pine leaching-vats, each of 50 tons sand capacity, the usual vats for strong and weak solutions, zinc-boxes of the individual bucket type, one centrifugal pump for returning solutions, and a four-foot Pelton water-wheel, from which the whole plant was driven. It was what may be termed a ready-made plant of the simplest description.

The treatment as first practised was equally simple: Crushing to two-inch maximum, reduction in water in the battery through a diagonal-slot screen with openings corresponding to 24-mesh, passage of the pulp over the amalgamating tables and through a trap at the foot, thence elevating about 25 ft. and discharging into the classifier, running the overflow to waste and the underflow to the distributor (by means of which the vats were in succession charged with sand), treatment by leaching for 10 days or more, followed by solution and water washes, and final sluicing out. It would be a waste of time and space to describe in further detail the treatment that followed, as it was the familiar round in use at the time in most of the small cyanide plants of the world. The fact that owing to scarcity of lime, caustic soda was used for counteracting acidity, may be worth mentioning. Another reason for this was that when lime was fed to the battery, gypsum was formed by combination with the sulphates in the ore, clogging the screens and building up on any exposed iron or steel surface. Caustic soda was easily obtained in the Manila market, at a reasonable figure, and proved fairly satisfactory, except that whenever the alkalinity became low in the leaching treatment, gelatinous precipitates of iron and aluminous hydrates would form and enter the extractors, thereby causing much trouble. Later on, when lime became plentiful, it was substituted for caustic soda, being added mostly in the treatment-vats, after amalgamation and classification.

The initial recovery made by this plant, working on fairly well oxidized ores from near the surface, was poor, but even at that it was better than anything that had

been done in the Islands up to that time. About one-third of the gold was caught by amalgamation, and of the gold in the sand about 70% was recovered by leaching. It soon developed, however, that the slime overflowing the classifier, and amounting to nearly 40% of the ore, was of better grade than the sand (even at times exceeding in value per ton the original ore). This naturally led to the introduction of slime treatment, with an attempt, in the meantime, to impound the slime until the necessary equipment could be provided. This effort was unsuccessful, because the climate and topography were unfavorable, but a plant consisting of a pair of vats with stirring mechanisms that could be raised and lowered was put into operation as soon as possible, and gave very satisfactory results in spite of its small capacity. The vats were alternately charged, settled, and decanted, solution added, charge agitated from 12 to 14 hours, settled, solution decanted to precipitation, fresh solution added, charge stirred and allowed to settle, solution decanted, and so forth, there being from three to four additions of solution followed by one of wash-water and final discharge through a door at the bottom. This represented a round of treatment quite fashionable at the time. It is to be noted that no fresh cyanide was used in the slime treatment, the strength of the solution from the weak circuit of the mill, containing about 1½ pounds of cyanide per ton, being sufficient. The recovery was from 80% to 90% of the gold in the slime, which added materially to the percentage recovery of the plant. The principal difficulty arose from the slow settling of the pulp, and low final density, thus limiting the capacity and holding back the rest of the operations. In the meantime, better precipitation facilities had been furnished by building regular double-line compartment wooden zinc-boxes, using imported redwood. The buildings, at first covered by grass thatch, were roofed with galvanized corrugated iron.

Concentration experiments on the material leaving the plates, and on the treated sand, yielded a product of about \$100 per ton from the former, and of about \$30 from the latter. These results led to the addition of a Wilfley table over which the classified sand passed on the way to the leaching-vats. By this means, a small amount of high-grade concentrate was recovered, the recovery in the leachers improved, and the time of treatment shortened. The concentrate was stored and shipped to the Selby smelter, at San Francisco, for treatment. It assayed somewhat over \$100 per ton, and contained some amalgam and quicksilver that had escaped the trap. An

incomplete recovery of these was made later by passing the stream of concentrate through a riffled launder over amalgamated plates.

The plant, as thus constituted, worked steadily for several years. A second battery of three stamps, identical with the first, was added in 1908, but, owing to lack of capacity in the cyanide plant, was operated mainly on old stope-filling and other fairly well oxidized material, inexpensively mined, and yielding more than 50% by amalgamation only. The average grade of ore sent to the first battery was from \$16 to \$18 per ton, and of that to the second, from \$8 to \$10. It is apparent that the loss in the tailing from the mill was high, but in view of the situation and limitations of the enterprise, working 'on a shoe-string' and necessarily self-supporting, the results, bad as they were, kept things going and yielded a profit. The major portion of the ore treated was from development, and the mill served a useful purpose in furnishing data on the proper metallurgical practice. Its destruction by flood in 1910, while apparently a great calamity, and indeed a sad and serious affair to those interested, was probably a blessing in disguise.

With a view to increasing the capacity and saving of the mill, a Ridgeway filter of the 'spider' type, with accessory apparatus, was purchased, but it had just been put into operation when the flood occurred. Therefore no data on vacuum filtration were obtained that would serve in planning for future work beyond demonstrating that a cake of satisfactory thickness and dryness could be made. The filter worked smoothly during the extremely short time it was in operation, and probably would have justified its use by increased output and saving. It was fed from a receiving-vat above, of the same capacity as one agitator-vat, the agitators discharging alternately into this after several decantations of solution. After continued settling, additional solution was removed by decantation from this receiving-vat.

The flood destroyed most of the cyanide plant, but left the stamps and plates and water-wheel. During 1911 and 1912 these were operated fairly steadily on an accumulation of low-grade dump-material that had become partly oxidized, and therefore yielded fairly well to amalgamation. Mixed with this was more or less old stope-filling (from primitive workings near the surface) and a certain amount of high-grade ore stoped from the mine and added as 'sweetening'. This period was ended by a second flood in the fall of 1912, which not only removed the remainder of the plant, but the site as well. In 1914 the property was re-financed, plans were made for building a new plant (after experimentation in the States, conducted on a shipment of ore), and the work of erection started late in that year, on an entirely new site, well above, and protected from, the stream. This plant, to be operated by a hydro-electric plant, included in the plans for rehabilitation, was designed to treat 60 tons per day by fine grinding and cyaniding, without amalgamation. It included the following equipment: One Hercules Blake rock-breaker, 8 by 12 in., preceded by a grizzly, 3 by 8 ft.; one ore-bin of 100 tons capacity, carrying the

grizzly and breaker, and preceding the stamps; two suspended Challenge feeders; one unit of 10 stamps of 1050 lb. each, with two single-discharge mortars, set on concrete blocks; one tube-mill, 6 by 10 ft.; one Dorr duplex classifier; one belt-and-bucket elevator; one 10 by 8 in. two-cylinder single-acting vertical air-compressor; one 6 by 8 in. horizontal wet-vacuum pump; two 4 by 6 in. Goulds all-iron triplex pumps; one steel clarifying-vat with 18 canvas leaves, each about 5.5 by 8 ft.; three steel zinc-boxes of two lines of seven (2-ft. square) compartments each; full equipment of vats for continuous counter-current decantation, comprising one primary, and four secondary thickeners with tanks 25 by 12 ft., three Dorr agitators with tanks 14 by 10 ft., one sump-tank, 12 by 10 ft., and one storage-tank 25 by 12 ft. (all of corrugated galvanized steel), and one Goulds No. 4 diaphragm-pump for each thickener except the last of the series; one wooden tank, 5 by 5 ft., fitted with a nozzle-outlet and a Bristol recording gauge; one automatic-tipping tailing-sampler, one Hampton improved zinc-lathe; one emery-wheel; and a clean-up and melting equipment consisting of one small wooden receiving-vat, one small vacuum-tank, drying-pans, etc., and one No. 125 Case melting-furnace. The crusher was driven by belt from a 10-hp. motor; the stamps, all on one shaft, from a 25-hp. back-gear motor; the tube-mill by belt and friction-clutch pulley from one of 50 hp. (with the elevator and classifier on a shaft driven by quarter-turn belt from the counter-shaft of the tube-mill), the compressor driven direct by belt from a 15-hp. motor; the primary thickener, agitators, wet-vacuum pump, zinc-lathe, emery-wheel, and triplex pumps all from another motor of 15 hp.; and the secondary thickeners with their diaphragm-pumps from one of 3 hp. The entire plant was roofed with corrugated galvanized iron, and the reduction, precipitation, and refining departments enclosed in plain galvanized iron, the rest being left unenclosed. The galvanized corrugated vats (the bottoms of which were of smooth galvanized steel) were all riveted, soldered, and carefully painted. This plant began operations in September 1915, and, with the additions and alterations herein noted, has been in steady operation ever since.

The plan of operation was as follows: The ore, brought from the mine through a new cross-cut, was dumped, without weighing or sampling, over the grizzly, the oversize going through the rock-breaker, set to a two-inch opening, thence dropping into the 100-ton bin back of the stamps. From the bin it passed to the feeders through chutes with regulating wooden gates, thence to the stamps, the stock cyanide solution being added in the battery in the proportion of 5:1. Rectangular steel screens of from one-eighth to one-fourth inch net width of opening were used, the coarseness being varied to balance the work of the stamps and the tube-mill as nearly as possible. (Experience soon showed that a considerably coarser screen could be used to advantage.) The pulp was carried from the stamps by launder to the Dorr classifier, in closed circuit with the tube-mill, wherein grinding was carried

to minus 100-mesh. The pulp, with about 6:1 dilution, was elevated and discharged into the primary thickener, the overflow from which went to precipitation after clarification, while the underflow, lifted a few feet by the diaphragm-pump, entered the first of the three agitators, thence through the second to the third, and thence to the first of the secondary thickeners, the overflow of which was returned by one of the triplex pumps to storage. The pulp passed progressively through the secondary thickeners, meeting in the first three the counter-current of wash solution, and in the last, a water wash. The barren solution from precipitation, handled by the second triplex pump, joined the pulp as it went to the third of the secondary thickeners, being augmented in volume by the overflow from the last thickener. After sampling, the stream of pulp was run to waste.

A continuous record of the flow through the zinc-boxes was obtained by means of the small receiving-vat and Bristol gauge, the latter recording the head at all times during the day on the centre of the discharge-nozzle. From this was figured the average head for the day, and by using a chart showing the flow for various heads through the nozzle in use, the total tonnage passing was easily and accurately determined. Frequent pulp and solution samples were taken throughout the mill, the tonnage of ore treated being calculated, with occasional weighing of cars as a rough check.

At first the cyanide strength in the agitators was maintained at about $1\frac{1}{2}$ lb. per ton of solution, by the addition of cyanide to the pulp as it entered the series, but it was found soon that this strength could be reduced to one pound or less, with equally good results and lower cyanide consumption, and that the best point to add fresh cyanide was at the head of the tube-mill, in which, owing to the working in closed circuit with the classifier, a concentration of the precious metals occurred; by maintaining the cyanide strength at from 1.5 to 1.8 lb. at the discharge end of the mill, a very effective selective treatment of the sulphide and other heavier and higher grade constituents of the ore was obtained, while the strength of solution from this point onward was sufficient without further additions of cyanide, to secure maximum dissolving and ensure good precipitation.

Lime for maintaining protective alkalinity was at first scattered by hand on the dry ore going to the feeders, but this method proving unsatisfactory, a mixer of the Chilean mill type was built on the ground, and installed above the battery-floor. From it a thick emulsion of lime in cyanide solution is fed to the batteries, the quantity of lime being regulated by the flow of cyanide solution.

In order to reduce the loss of dissolved metal and of cyanide in the tailing, as well as to increase the time of contact with the cyanide solution, a Trent replacer was installed below the last thickener of the series. The stream of barren solution was then added to the pulp as it entered the last thickener, and the underflow from this thickener, going to the replacer before being discharged, received therein a wash by replacement with water. This change reduced the tailing loss.

In the reduction end of the plant, the need was soon felt for preliminary classification in advance of the Dorr classifier, to relieve it of handling such a range of product, by removing the bulk of solution with the lighter slime, and, as coarser battery-screens were used, of the coarser portion direct for tube-milling. Upward-current pyramidal classifiers, using cyanide solution, were first tried for slime elimination, but proved rather unsatisfactory on account of excessive dilution and diffi-

NATIVES AT WORK UNDERGROUND

culty of regulation, and a drag-classifier of the Esperanza type, built on the ground (as were the pyramid classifiers) was installed to accomplish the second result. The changes made later and herein described relegated the upward-current classifiers to the scrap-heap, by providing sufficient capacity in mechanical classification.

The plant was originally designed to handle 60 tons per day; it was soon shown in practice that this could easily be exceeded in the reduction end, but the capacity of the treatment plant was less, owing to the high grade of the material, the slow settling of the slime, and the protracted dissolving of a portion of the precious metals. In order to secure greater capacity with longer contact and better results, a second line of treatment-vats was added. This series consisted of a 30-ft. Dorr thickener, supplied by a belt-and-bucket elevator and served by a No. 4 Goulds diaphragm-pump; a 25 by 18 ft. Trent agitator with 5-in. centrifugal slime-pump, and two Trent replacers, each 24 ft. in diameter at the top, 20 ft.

at the bottom, and 14 ft. deep, with 4-in. centrifugal circulating pumps. One 6 by 8-in. Goulds triplex pump and an additional sump and storage-vat were added. Three more double-line zinc-boxes more than doubled the precipitation capacity, while the facilities for handling the product had previously been increased by the installation of a filter-press, served by a rotary pump. In the refinery the furnace equipment was duplicated and a laboratory crusher, grinder, and baby Wilfley table added to reduce and concentrate the slag.

It was planned to use the new series in parallel with the old, with the old replacer in common, for washing, either by splitting the pulp between them in the proportion of their demonstrated relative capacities, or by giving to each the product best suited to it. Practice soon demonstrated, however, that better results could be obtained by working the various units in series, as shown in the flow-sheet of the present practice. It would have been interesting to have been able to obtain, over long periods, comparative figures on the working of counter-current and replacement, working side by side in the same plant, had economic conditions permitted.

The final addition to the treatment, made in 1919, consisted of an Oliver filter, 12 ft. diam. by 18 ft. long, with the usual accessory apparatus, and a 25-ft. Dorr thickener in advance of the filter. These additions brought the capacity of the treatment plant up to a point where further additions and improvements were needed at the reduction end, so, last year, another tube-mill, 6 by 8 ft., was added, together with a washing, screening, and classifying system, whereby the coarse ore was separated from the fine previous to stamping, the slime carried directly to treatment, and the work of classification much facilitated and improved. The units comprising it are described in the summary of present practice, which follows:

The ore is a mixture of quartz, iron oxide, and sulphide, altered diorite, and clay; quartz predominates over the other gangue-minerals, and the iron sulphide now greatly exceeds the oxide in quantity. There is some free gold, but none is visible. Some of the sulphide may be of primary origin, but it is likely that the greater part of it is secondary, even though much of the ore appears to be unaltered. The kaolinization apparent in much of the ore is evidence of strong secondary action. The clay in the ore comes mostly, however, from the gouge on the walls of the vein. Most of this is discarded in mining, but in places it is highly mineralized, and in others mining conditions makes it impossible to eliminate it. The partly altered diorite, considerably silicified, alongside the ore-shoots, is often sufficiently mineralized with gold-bearing pyrite to warrant its inclusion with the run of mine. Some silver is associated with the gold, the bullion returns showing a recovery of about 1:3 by weight. The ore shows slight traces of copper at times, and possibly of lead, the former as a silicate or carbonate and the latter as galena, but not enough to affect the treatment in any way. The supply of ore now comes entirely from the levels below the mill-level, through a

vertical shaft, directly back of the mill. It is weighed underground, hoisted, and dumped on a grizzly, 8 ft. long by 7.5 ft. wide, set at an angle of 50° from the horizontal, over a receiving-bin, which also carries the rock-breaker, moved back to this position. The combined product from the grizzly and breaker is fed by a reciprocating plunger-feeder from the bin to an inclined elevator, of the close-connected bucket type, which lifts it about 25 ft. and discharges it into a revolving trommel 4 ft. in diameter by 6.5 ft. long, set at an inclination of 1.5 in. per foot, and driven by bevel gear. Spray-pipes near the top on each side furnish weak solution for washing the fine and clay from the coarse. The oversize, well-drained and quite free from clay except such chunks as ball up, falls directly from the washer into the bin behind the stamps, and thence is fed through the chutes and feeders into the batteries. The product that passes the screen of the trommel drops directly to a Dorr duplex classifier, one of a battery of three, set sufficiently high to allow the slime to overflow by gravity to the primary thickeners. The one classifier first mentioned, however, is set higher than the other two, in order to enable the overflow to be divided between the other two if desired. It is to be noted that a second trommel, of dimensions smaller than the one mentioned, and furnished with a finer screen, was included in the system, with the idea of providing a direct tube-mill product by screening, but this is not being used, the classifiers evidently accomplishing the work sufficiently well. It is also to be noted that lime is added at the washer in an emulsion supplied by a mixer identical in construction with the one already mentioned in connection with stamping. The screen covering of the trommel is of punched sheet-steel, with elliptical holes, 0.25 by 0.75 in. (the original plan contemplated using screens of five-eighths inch net openings on this trommel and of five-sixteenths on the second one).

The discharge from the stamps, through screens having openings ranging from 0.5 to 0.75 inch, goes to the drag-classifier, which sends a coarse product to the head of the longer tube-mill, while the slime-overflow joins the discharge from this mill, to be elevated and divided between the two secondary Dorr classifiers, or delivered to either of them. (One of these classifiers is the one formerly used in closed circuit with the 10-ft. mill, but moved up.) The coarse product of the primary Duplex classifier, mentioned as receiving the undersize from the trommel, goes by gravity to the head of the shorter tube-mill, the discharge from which flows to the foot of another elevator, delivering to either or both of the secondary classifiers. The arrangement of the elevators is such that either can receive the flow from either or both mills and from the drag-classifier overflow, and discharge to either or both of the secondary classifiers, the head product of which can go by gravity to either or both of the tube-mills, thus constituting an elastic system in closed circuit.

The combined overflow from the classifiers is carried by gravity to the 30-ft. thickener, from which a clear

overflow of pregnant solution is taken for precipitation after further clarification, while the pulp, thickened to 1.25:1 is drawn and lifted to a launder from which after dilution to 2:1, with fresh barren solution, delivery is made to the Trent agitator through the suction of the 5-in. circulating pump of that machine, the suction-pipe being carried vertically alongside the tank, and to the level of the top. Thus the static head is utilized, and a

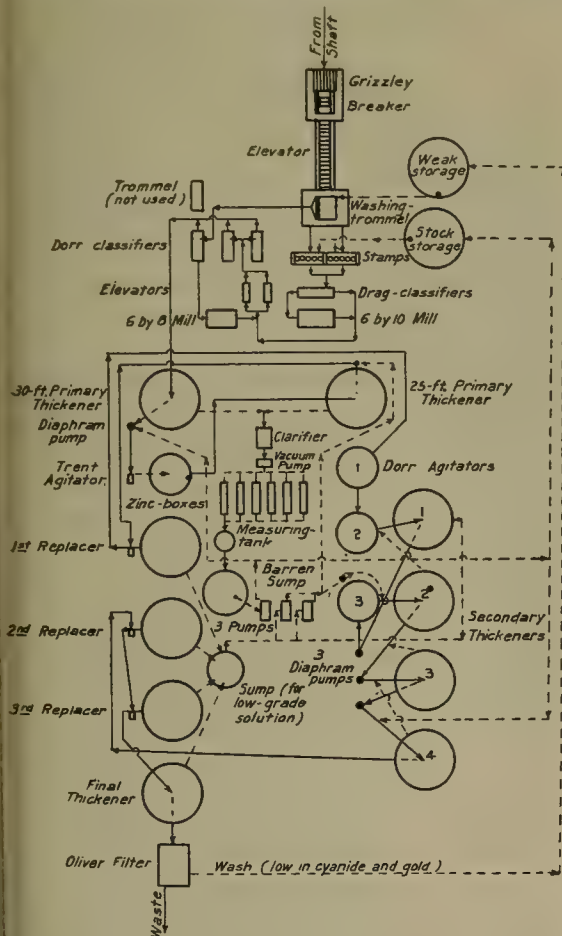

additional solution being added before it reaches the thickener, unless more is required to furnish the desired amount for precipitation than the normal overflow from the two primary thickeners.

The underflow of pulp from the 25-ft. thickener is lifted by a diaphragm-pump, diluted with low-grade solution to a 3:1 ratio and run to the first of the Trent replacers, which it enters over an umbrella-shaped device for preventing undue disturbance of the surface of the charge. This distributor is set in the centre of the vat, with its edge flush with the surface, so that the pulp particles begin settling at once, while the incoming solution, mingling with the clear solution on top of the charge, overflows into an annular launder. The pulp thickens in the bottom of the vat, where it is kept in circulation by the centrifugal pump, connected like the one serving the agitator, except that the return connection from the vat to the pump-suction is situated about two feet above the bottom of the vat. Fresh solution is introduced into the pump-suction and intimately mixed by the pump without disturbing the upper or settling-zone, and a steady withdrawal of pulp from the pump-discharge, at a ratio of 2:1, is made to the first of the Dorr agitators, the volume being regulated by a valve in the 2-in. line. The passage of the pulp through the Dorr agitators, with a thickening before the final agitation, has already been described. The progress through the thickeners is as herein indicated, but it has been found advantageous to vary the flow of solution therein as shown on the flow-sheet, thereby getting better washing and quicker settling.

From the last of the secondary thickeners, the pulp is discharged by static pressure to either one or both of two Trent replacers. These usually are operated in series, but they can be operated separately or in parallel. In them the pulp is further washed by replacement with fresh barren solution, and finally discharged at a ratio of 2:1 to the thickener preceding the filter. No further dilution is made to the pulp entering this thickener, as its principal function is to furnish a supply of properly thickened pulp to the filter. The solution overflowing from this thickener joins the combined overflow from the last two replacers. A portion of this mixture of low-grade solution is used on the first replacer, while the remainder goes to storage.

On the filter, a barren solution is used on the upcoming side, and a water-wash on the downgoing side, the cake discharged containing about 25% moisture. It has not been in steady operation long enough to enable exact figures to be quoted in this article, but those available indicate a capacity of about 140 tons of dry pulp per day, with low losses in cyanide and dissolved precious metals.

The plant now handles from 110 to 120 tons of ore per day, assaying \$20 per ton. The total recovery is about 90%, the percentage increasing with an increase in the value of the ore, as a rule, and within certain limits, dependent on the character of the ore. If this contains most of the uncombined metal, a very slight rise in the residue of undissolved metal follows a rise in the value of the heads, but if there is much telluride present, the rise

FLOW-SHEET OF MILL

mixture of atmospheric air, essential to the operation, is drawn in with the pulp. The suction stand-pipe is connected by a branch through the side of the tank, about two feet from the top, whereby pulp from the charge is drawn into it, mixing intimately in the stand-pipe and sump with the incoming pulp and air. Delivery is made from the pump through the bottom of the vat to the distributing arms and mechanism. The volume thus circulated every hour is approximately equal to the volume of the contents of the vat, while the volume entering is about one-twentieth of this, thus securing about 20 complete reverts of the tank before passing on to the 25-ft. primary thickener. (If more air is desired in the agitation, it is admitted through a pet-cock in the pump-suction.) The discharge from the agitator is through an open pipe through the side of the vat at six inches from the top, no

is very marked. It is apparent from the foregoing description of the treatment that an unusually long contact with cyanide is secured and many additions of fresh solution made during its course, with the result that there is very little loss in dissolved gold or silver, but the loss in undissolved metal has always been and is still rather high. The justification for such long-continued treatment lies in the fact that whereas about 80% of the assay-value is dissolved readily in the first stages of treatment, there is a residue that resists stubbornly the action of cyanide, the result being a slow but continued dissolving that lasts throughout the treatment. From the time the ore enters the mill until it is discharged is about seven days, which should be ample for almost complete dissolution of the precious metals were it not for the fact, well-established by experimentation, that there is a definite amount of gold and silver in combination with tellurium. Repeated experiments on the tailing disclose the facts that the slime portion (finer than 200 mesh) contains the major part of the undissolved metals, and that, whereas the concentrate from the tailing stream has a value of about \$30 per ton, the percentage represented by this is so small as to account for considerably less than half the loss. It is evident, therefore, that it is mainly due to the presence of very finely disseminated high-grade mineral, with the gold and silver in combination; so that concentration offers no remedy. Experiments have been made on the tailing by flotation with indifferent results (the pneumatic method being used), and laboratory experiments on the concentrate recovered from the tailing by panning or table-work, including re-grinding and re-treatment with stronger solution, have invariably shown poor dissolving action with heavy loss of cyanide. A recent series of experiments conducted in the United States on a lot of concentrate recovered from the tailing upon a small Wilfley table gave no better results, but a re-concentration of the concentrate yielded a product, cut from the extreme upper edge of the table-flow, that represented 0.638% of the total; this assayed 41 times as high in gold, and analyzed 0.5% in tellurium. It represented but a very small fraction of the loss in the tailing, but its segregation is of great interest as showing in a magnified way the undoubted presence of tellurium, which, by the way, was present in this product in a much greater proportion to the gold than called for in any mineral combination of the two. This is explained on the assumption that a considerable proportion of the gold originally combined with this tellurium had been dissolved during the course of treatment.

It is apparent, therefore, that the treatment of this ore presents difficulties that are hard to overcome, and that while they have received careful consideration from those in charge, with improved results, there yet remains the problem of increasing the dissolving action without too greatly increasing the cost or prolonging the treatment beyond the point of economy. No re-treatment scheme suggested so far appears to be practicable or profitable. No doubt, if the topography and climatic conditions permitted the impounding of the tailing, nature would soon

break up whatever combinations may exist, but it would result in so many oxidation products harmful to cyanide that it is doubtful if re-treatment would be profitable. It is likely that if a method of increasing the recovery be found, it will be within the limits of the present treatment, rather than in the addition of other methods preceding or following.

Vanadium Corporation

The Vanadium Corporation of America announces that its total income after all charges, taxes, etc., amounted to \$1,319,513 for the six months ended June 30, 1920. The gross sales during this period amounted to \$5,966,046. The first of the year it took over the Primos Chemical Co., a producer of tungsten, molybdenum, and vanadium with mines in Colorado and a treatment plant at Primos, Pennsylvania.

The vanadium properties are situated at Minasragra, Peru, in the Andes mountains at an altitude of 15,800 ft. They are reputed to be the richest and most productive deposits in the world and produce 80% of the world's supply. The roasted ore was formerly carried on the backs of llamas to the railway, but at the present time the Foundation Co. is constructing a 6-mile 30-in. gauge railway from the mines at Minasragra to Lake Pun Run. From this point the ore will be ferried 9 miles across the lake on 25-ton barges and loaded on motor-trucks for transportation to the railway at Rinceran, a distance of 15 miles. The present production will be greatly increased when this railway is completed. The vanadium occurs in the form of patronite and is mined by open-cut workings. This ore is roasted and packed in 125-lb. sacks and shipped to America. The ore-reserves are estimated to amount to about 38,000,000 lb. of vanadium or a 20 years supply, the amount being approximately 100,000 tons and the grade 19% vanadium.

It is proposed to erect a treatment plant at Jumasha on the shore of Lake Pun Run to concentrate the ore and ship a product running 80% vanadium oxide.

The smelter at Bridgeville, Pennsylvania, is equipped with two electric furnaces capable of producing 75,000 lb. of vanadium from the re-treatment of the slag accumulation of many years, besides an aluminum reduction process for the roasted ore. At Vanadium, Colorado, the Primos company operates a vanadium mine and reduction plant, another vanadium mine at Placerville and a third mine at San Pete. A molybdenum mine and mill are situated near Empire, Colorado, and in Boulder county, Colorado, it operates a number of tungsten mines and a large concentrator. The concentrates from all these properties are shipped to the treatment plant at Primos near Philadelphia, Pennsylvania.

Vanadium finds its chief use in the manufacture of alloy steels, where it has met with great success ever since its introduction in 1905. Molybdenum is also used for alloying with steel. Tungsten is used for steel making, in the manufacture of lamps, and other industries.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

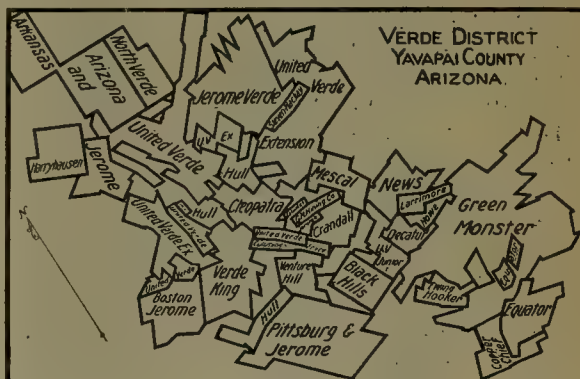

SHATTUCK ARIZONA COPPER REPORT.—UNITED VERDE WILL NOT CURTAIL FURTHER.

BISBEE-WARREN.—The report of the Shattuck Arizona Copper Co. for the quarter ending September 30, 1920, shows a loss for the quarter, exclusive of depletion, of \$19,109. The report says in part: "Lead mining and milling operations have been conducted at nearly full capacity of the concentration plant. The production of copper, and of gold and silver from copper ores for the quarter, was less than previous quarters due to less copper ore mined. The production of lead, and of gold and silver from lead ores, was considerably more than in the previous three months due to more tons milled and to better grade." During the quarter the company produced a total of 2,405,250 lb. of lead, 527,454 lb. of copper, 137,164 oz. silver, and 1436 oz. gold. A total of 2150 ft. of new development work was done during the quarter. The company laid off about 100 men on November 24, and will shut-down completely as far as mining operations are concerned, on January 1. At that time the entire force, with the exception of about 40 men who will be retained to carry on development work, will be laid-off. The Denn Arizona Copper Co., which is under the same management, has been shut-down since November 1.

The Calumet & Arizona Mining Co. is maintaining its force and contemplates no reduction that will effect underground operations. The company is employing a few men but is making no effort to increase its present working force. The Copper Queen branch of the Phelps Dodge Corporation will continue operations on the present basis, and does not at present contemplate making any reduction in its working force.

JEROME.—The recent visit of Charles W. Clark, general manager for the United Verde, to the company's mines in Jerome, has set at ease the minds of those who were apprehensive of a complete shut-down of the mines and smelter. Mr. Clark is reported as being decidedly optimistic as to the future and as expressing the opinion that a general improvement in conditions will probably take place early next year. In the course of an interview, Mr. Clark is quoted as having said: "The United Verde company has a splendid organization and we would break it up only with the greatest reluctance. We would much prefer to run along as at present for several months, even at a loss. Today we are employing approximately 60% as many men as we did at the peak of war production,

and are turning out about 40% as much copper. We will cut down the force only a very little bit more here at Jerome. It is possible that we will suspend steam-shovel operations entirely for a short time. At Clarkdale there will be no further curtailment; two furnaces will be kept going. Positively there will be no shut-down. We have no intention whatever of closing our mine and smelter. On the contrary we have high hopes that in a month or so we can begin gradually to put on men." Mr. Clark

also expressed optimistic views anent the labor situation, and in regard to the likelihood of an early wage-cut in the copper industry is reported to have said: "Such a thing has never been discussed by Arizona copper producers. I read that Michigan companies have reduced wages 15% but no such step is contemplated here. Of course, in the general readjustment wages will probably have to come down along with the products of the country."

Some speculation as to whether the Jerome-Verde was considering the resumption of active operations was created by the presence in Jerome of I. Mabbett Sutton, secretary of the company. Mr. Sutton, however, gave it as his impression that development work would not be resumed for at least a year, adding by way of explanation that "wages and materials are so high that we cannot consider resuming development at this time, though we would like to do so in preparation for the time when copper will be back to normal prices".

Steam-shovel operations at the United Verde Copper Co. are reported to have uncovered an orebody approximately 75 to 100 ft. wide, lying west of the former office building. The size of the orebody has not yet been ascertained, but the contents are said to assay over 4% copper. Important changes are said to be contemplated by the

Western Chemical Co. in regard to the development and operation of its sodium-sulphate deposit south-west of Camp Verde. It is probable that, instead of shipping the sulphate as extracted, the company will set up a washing-plant on the ground. This equipment is expected to arrive shortly after the first of the year. The necessary water will be piped from Copper canyon or pumped from the Verde river. The process in general will consist of grinding the sulphate to powder, washing out the dirt, allowing the remaining sulphate to crystallize and then sawing it into blocks for shipping. Considerable development work has been done, and the results indicate a large reserve of sulphate.

COLORADO

VANADIUM ORE DISCOVERED NEAR TELLURIDE.—STEEL FOR SMUGGLER UNION MILL ARRIVES.

CENTRAL CITY.—The Coeur d'Alene property was recently visited by T. H. Jenks, consulting engineer for the National Finance & Holding Co., of Toledo, Ohio, who completed arrangements for resumption of work. This property is an early-day producer with a record of better than \$155,000 mined from shallow workings. The deepest shaft is but 400 ft. deep. G. E. Bolander, of Black Hawk, has been engaged as superintendent and a force has been put to work re-timbering the shaft, repairing mine buildings, and overhauling machinery.

J. Larsen, of Denver, and associates are unwatering the Ridgewood mine. The property has been long idle, but the shaft-timbers to the water-level were found in good condition.

CRIPPLE CREEK.—The new station at the 2450-ft. level of the No. 2 shaft of the Portland Gold Mining Co., on Battle mountain, is nearing completion, and cross-cutting will shortly commence, to prove the continuation of the rich ore now under development on the two levels above the 21st, corresponding with the Roosevelt tunnel-level. Foundation for the hoist, formerly in operation at the Gold Coin shaft of the Granite company at Victor, has been completed. A new screening plant is also being installed. The Independence mill continues operating on low-grade ores, the higher grades being shipped to the Golden Cycle mill at Colorado Springs.

IDAHO SPRINGS.—The Denver tunnel at Empire is being re-timbered preparatory to the resumption of work. The bore has been driven 1800 ft. and ore of a milling grade is reported in the breast. The vein will be opened by drift and shipments will commence the first of the next year. The Gem mine is producing mill-ore in tonnage sufficient to keep the Newton mill operating on two shifts.

The Elliott-Robinson company has a force of miners employed cleaning out and re-timbering the Silver Age tunnel. The tunnel, a former producer of high-grade ore, but long idle, was found badly caved; it will be made safe before operations are resumed. The shaft at the French Flag mine is being unwatered preparatory to resumption. The Columbia mine at Empire is again active and a promising ore-shoot is reported by F. E.

Birdsall, operating the property, as having recently been opened by a drift. Ore is now being saved for shipment.

LAKE CITY.—The Standard Mines Development Co. reports a rich discovery of gold-silver ore in one of the old tunnels on the Little Chief; samples assay as high as 22 oz. gold and 1200 oz. silver per ton. A camp has been established at the mouth of this tunnel, two miles from Lake City, and ore is being saved for shipments to start December 1. The Little Chief is owned by the Thatcher estate and is operated under lease and bond. Christie and Atkins, of Lake City, operating the Ute mine under lease from Samuel D. Nicholson, of Leadville, have opened up high-grade ore and have made two shipments. The ore now being mined is reported the richest mined in the San Juan for the past 20 years. No figures, however, are available.

The Goldona Mines Co. has acquired the Dewey No. 2 lode, the Bob Ingersoll, and other claims adjacent to the Golconda group, and will continue operating this winter through the Dewey No. 2, situated on the Hurricane basin side, which is more accessible. Rich ore has recently been found. Plans for development by a long cross-cut tunnel have been perfected and will be started while blocking out of ore-reserves for spring shipment is continued.

LEADVILLE.—A 'grass-root' discovery is reported from the Sugar Loaf district on the Fanchon placer. Ore assaying as high as \$200 per ton in gold has been opened by lessees on the Fugan section of the placer. The extent of the orebody has not yet been determined.

SILVERTON.—The rich ore recently opened on the Ariadne persists with additional drifting; the force of miners will be increased when stoping ground is opened. The Iowa Tiger continues steady production for its mill and a good grade of concentrate is made. Operations will be resumed by December 1 by the Gold King Extension Mines Co. with a larger force than when the property closed temporarily last month. Good orebodies have been opened on the Gold King and other properties and reserves available will keep the Gold King mill in continuous operation for a long time ahead. Rich ore is reported exposed in the tunnel on the Eastern Star mine although details of the discovery are not yet obtainable.

TELLURIDE.—The Colorado Vanadium Co., following discovery of vanadium-bearing ore in the White Cliff near this city, has had its geologist and surveyor in the field and has made several locations. Henry Williams, who made the original discovery, appears to have located the ground carrying the strongest visible vein and may realize ample funds to keep him in comfort the remainder of his life. He is 70 years old and has for many years searched for a phantom 'lost lode' of gold ore. Scores of locations have also been made by citizens, business men, and miners in Telluride. Structural steel for the new flotation plant of the Smuggler Union company, contained in nine railroad cars, has been unloaded here and hauled to the mill-site. Other material and machinery has been sent forward and the contractors expect to have the building completed and machinery installed early in the spring.

MICHIGAN

COPPER RANGE MINES WILL NOT CURTAIL.—PRODUCTION AT MOHAWK AND WOLVERINE PLANTS IS BEING INCREASED.

CALUMET.—The extent of the curtailment at the Calumet & Hecla mines and the readjustment in all surface departments, including mills and smelters, indicate that production of these properties will continue at an unusually low figure for the next six months. The Hecla mill has been closed and all 'rock' will be stamped in the Calumet mill. That plant will operate at capacity on conglomerate 'rock'. The reclamation plant has not curtailed and the output from this department will continue around 1,000,000 lb. of copper per month. The reduction by the parent mine will be about 600,000 lb. per month, representing the output from the Osceola lode branches. Surface forces are being reduced about 50%. In some of

September and was exceeded during the past six months only in June. The output of Calumet & Hecla's conglomerate department was 2,753,891 lb.; the reclamation plant recovery was 1,057,735 lb.; and the Osceola amygdaloid branch produced 735,333 lb. This is an improvement of 332,535 lb. for the reclamation plant over September but it is 300,000 lb. below the figures for May and June. Isle Royale's October production was 831,700 lb., compared with 727,864 for September, while LaSalle reported 14,413 lb. for October. Superior's October operations yielded 38,066 lb. and White Pine produced 76,000 lb., a decrease of about 5000 lb. from September. The total output for the Calumet & Hecla group was 7,943,502 lb., compared with 7,288,214 in September.

The Copper Range mines will not curtail forces. On the other hand a small number of men are being taken on at Champion and Trimountain. Production is now but

INTERIOR OF A MICHIGAN CONCENTRATOR

the shops, at the employees' initiative, a half-time schedule is to be put into effect rather than curtail to a great extent in forces, with the men working three instead of six days per week.

The drastic curtailment by Calumet & Hecla reflects the demoralized condition of the metal market and the only hope for the restoration of normal conditions appears to depend on the absorption of the existing surplus. It is estimated that Calumet & Hecla has \$12,000,000 tied up in unsold metal. With the navigation season practically at an end there does not appear to be any likelihood that rail shipments in large volume will go forward inasmuch as high freight-rates add so much more to the cost of production.

The extent of the curtailment at Ahmeek and Isle Royale, the only other two mines of the Calumet & Hecla group now operating, has not been announced, but it is understood that Ahmeek's output will be such as to keep all stamping units at the mill in operation.

Ahmeek's October production in refined copper, 1,759,100 lb., is an increase of approximately 150,000 lb. over

little better than 50% of normal, but it is expected that this will be increased somewhat. Quincy also does not propose to curtail and is employing some additional underground men. Some of the Calumet & Hecla men have been taken by Mohawk, Wolverine, Quincy, and Copper Range. Seneca also has increased its force during the past ten days.

Wolverine has begun to return to normal production, with the pre-war peak as the basis, and within three weeks or a month, another head in the Wolverine mill likely will be started. Production of 'rock' is steadily climbing as the result of increasing the force of miners, trammers, and laborers. Wolverine has begun to take out the shaft-pillars, beginning at the 38th level, from which all bodies of profitable ore have been mined, and as other levels are completely stripped of commercial 'rock' the work will proceed upward. The removal of the pillars does not necessarily mean that the shaft will come together, yet if the explorations on other veins reveal ore it is not likely the pillars will be removed at present above the 28th level. The pillars, it is estimated, will bring

Wolverine's yield up to between 17 and 18 lb. per ton and this recovery likely will be maintained for the remainder of the mine's life, so far as the Kearsarge amygdaloid is concerned. There likely will be stretches of ground in the pillars that will be found remarkably rich and an immense amount of copper will be extracted from them, for the pillars are about 90 ft. square and extend from the surface to the bottom.

Mohawk is taking on fairly large numbers of miners, trammers, and laborers, including many former Calumet & Hecla underground men. As soon as the force is built up to completely man No. 4, 5, and 6 shafts, it is proposed to open No. 1, as well as push the development of the fissure vein between No. 4 and 5 shafts. The fissure has been opened for a distance of about 700 ft. south of No. 4 on the 22nd, 23rd, and 24th levels, and it has been found to be mineralized for a width of from two to three feet, chiefly in the hanging wall. There also is copper in the foot-wall in certain spots but the hanging-side yields the larger amount of mineral. The main walls of the fissure vary from a few inches to eight and twelve feet in thickness and in places the vein is found to be exceedingly rich. No. 1 shaft is bottomed on the 26th level but there are large tracts of ground on the upper levels that will be removed in widening out drifts and extending the stopes to the foot and hanging walls.

Instead of curtailing operations, as has been done by Calumet & Hecla, the Mohawk and Wolverine plants are to materially increase their forces in the hope of earning money by quantity production on a low market. Mohawk's output, accordingly, will be pushed to 2400 tons or more per day from Wolverine and it is proposed to maintain shipments at a rate of 1200 tons per day from Wolverine. This will necessitate the operation of practically all the stamps in the two mills, whereas, prior to two weeks ago, only the Mohawk mill was operating to crush all the 'rock' that could be mined from the two plants.

Arcadian Consolidated is still operating and the management expects to continue through the winter. The vein continues to appear in the shaft at intervals and wherever it is exposed as the shaft deepens there is a splendid showing of mineralization. The station at the 750-ft. level will be cut about the middle part of the coming week and a small drift, north and south, may be put in at that point. This level will be the only one to be put in on the sixth level to collect water that flows from the upper levels and as fast as it fills the water will be permitted to run into the bailers.

NEVADA

ORIZABA PROPERTY IS SOLD.—GOOD ORE FOUND ON THE 1100-FT. LEVEL OF THE RESCUE EULA.

ORIZABA.—The property of the Orizaba Mining & Development Co., 36 miles north of Millers, the shipping point, has been sold to a syndicate of New York men headed by A. M. Page, Bartlett Smith, and George B. Hutchins. The Diamondfield Black Butte at Goldfield also was sold as part of the deal. The Orizaba consists

of nine claims. The main vein is on a contact between highly metamorphosed limestone and an altered granite intrusive, according to a report made by J. K. Turner of Goldfield. A fault-fissure near the contact cuts and interrupts the ore-bearing vein, and where the drifts have followed the fault-gouge and breccia only low-grade ore has been found. The ore on the upper or 65-ft. level is stained quartz containing silver chloride and a little gold. On the lower level the ore consists of fine-grained quartz, some calcite, zinc sulphide, small quantities of galena, and silver sulphide. Two veins join with the main vein, but little work has been done in them. The development work totals 1300 ft. The main shaft, 120 ft. deep, contains water to 95 ft. from the surface. The shaft, sunk in or near the foot-wall of the vein, dips at 70°, about the same as the vein. Drifts on the 65-ft. level are 550 ft. long, 150 of which is east of the shaft and 400 west. Drifts have been driven 130 ft. east and 220 ft. west on the 85-ft. level. The west drift is caved from the 170-ft. point. An average of all samples assaying more than \$9, which is estimated to be the minimum for mill-grade ore, showed an average width of 3½ ft. and a value of \$19.32 in silver. The gold content is unimportant. Mr. Turner estimates that the dumps contain 300 tons of \$21.30, 3000 tons of \$11.80, and 300 tons of \$9.80 ore, a total value of \$44,730. Ore of a gross value of \$22,980 and a net value of \$16,155 has been shipped. The shipment contained 42.3 oz. silver per ton at 91½c. per oz. Mr. Turner advises that the use of steam-power be discontinued and that a new shaft be sunk in the hanging wall of the vein in order to avoid the water.

TONOPAH.—Ore in a vein five to six feet wide, assaying \$40 to \$60 for this width, has been found at a depth of 1100 ft. in the Eula claim of the Rescue Eula. The ore was found in a drift driven east on the foot-wall side of a flat-dipping vein 20 ft. wide. The vein is broken west of where ore was found, but the condition in the ore-shoot is good.

VIRGINIA CITY.—The tunnel of the United Comstock has been driven 100 ft. from the portal and three shifts of miners are continuing it at a rate of 15 ft. daily. The tunnel will be double-tracked and two 6-ton electric locomotives using storage batteries will be used for hauling. It is also planned to use a shoveling machine. The company is preparing to drive the tunnel from the Imperial, Belcher, Knickerbocker, and Jacket shafts. The surface plant at the Knickerbocker is practically complete, cross-cuts from the Belcher and Jacket are nearing points from which the tunnel will be started, and sinking of the Imperial shaft will be resumed in a few days. Zeb Kendall has been elected president of the Consolidated Virginia, Mexican, Ophir, and Union companies in place of Alex Wise, who hereafter will devote his entire attention to his position as superintendent for these companies.

PIOCHE.—The Salt Lake Route has announced a proposed reduction in rates as follows: \$6.50 ore, from \$2.75 to \$2.20; \$8.50 ore, from \$3.50 to \$2.80. Lower rates on this grade of ore are of great importance to the Pioche

companies, as they will permit shipment to Salt Lake smelters of much ore that otherwise could not be profitably mined.

COALDALE.—The Darms Coal Mining Co. will unwater the 600-ft. shaft and will use a diamond-drill at the bottom to prospect two veins that should be cut 50 and 150 ft. below the shaft. H. A. Darms has the largest interest in the company and Tonopah people are reported to have invested heavily to furnish funds for resuming work.

DIVIDE.—Drifts are being driven south-east on the 800 and 1000-ft. levels of the Tonopah Divide and the cross-cut on the latter is being continued through the vein. Important work also is being done on and above the 1000-ft. level.

GOODSPRINGS.—The employees of the Yellow Pine mine and mill have accepted unanimously a 50c. reduction in wages. Board was reduced 10c. when the wages were cut and prices will be reduced in a store operated by the company. The cause of the cut in wages is the low price of zinc ore.

LAS VEGAS.—The Tiffany mine near Crescent, a producer of turquoise, is being worked by the owners, J. B. Horne and Mrs. G. Jordan, who plan to eliminate the middleman in marketing the stones by employing a cutter. Crescent is on the Nevada-California line 15 miles west of Searchlight. Some of the stones when cut are said to be worth \$15 to \$35.

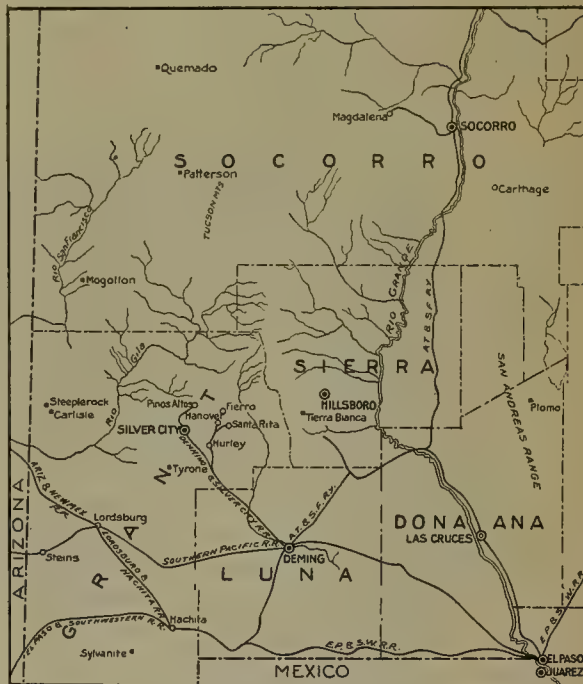

TYBO.—The smelter and mill of the Louisiana Consolidated have been closed because of a shortage of ore, according to reports, but development work in the mines is being continued.

EUREKA.—The following shipments over the local railway during the past week were consigned to the Utah smelters: by the Richmond-Eureka Mining Co., 21 cars of speiss; by the Eureka-Croesus Mining Co., 3 cars of ore, and the Eureka-Holly Mining Co., 8 cars of ore. The Eureka-Holly Mining Co. is timbering its shaft down to the 500-ft. level and is cutting out a station on that level and sinking its shaft deeper. Carpenters are progressing with the construction of the company's mill building. A new pump has been ordered by the Eureka-Croesus Mining Co., to be substituted for one hitherto used for pumping water from the bed of New York canyon. Ore is being extracted from four different places. Sinking continues in No. 8 winze, and a drift has been started on the ore-shoot. The management reports that these workings have furnished most of the 100 tons of ore that was shipped during the past week, and good ore is still showing at the bottom of the winze. Of the 100 tons, 50 tons was shipped last week and 50 tons this week. Ore continues in the 'shale' raise which is adding its quota to the shipments. The ore in No. 7 winze is reported to be holding out well, and five mine-cars are the average of the daily production. A raise has been started in the foot-wall of the old Dunderberg workings and is said to be in good ore. It is expected to ship 50 tons of ore from the mine next week and make a start for still another shipment. The winter's supply of powder and distillate for the mine has been received.

NEW MEXICO

NEW MILL AT RED ROCK.

SILVER CITY.—The Silver Spot Mines Co., organized in 1919 by Silver City capitalists, started operations in January 1920 on Boston Hill in search of the extension of the silver-bearing orebodies of Chloride Flat which made Silver City famous as an early producer of silver ores. Work has been discontinued owing to large quantities of water developed at about 150 ft. This made difficult the original intention of the company to sink to 300 ft. Development succeeded in disclosing the presence of silver-bearing ores, associated with manganese ores. Several carloads of the latter were shipped. The

SOUTH-WESTERN NEW MEXICO

company plans early resumption of work when arrangements are completed for handling the water.

WHITE SIGNAL.—Operations have been suspended on the radium-bearing ground at White Signal, where for several months the Radium Company of Colorado has been actively engaged in determining the extent and content of the torbernite ores. Development operations are understood to have been unsuccessful, owing to the fact that the torbernite ores were of low grade and presented difficulties in extraction which could not be successfully met by present metallurgical practice. The Co-Operative Mining Co. of Lordsburg has purchased all of the equipment used by the Radium Company of Colorado.

LORDSBURG.—A 200-ton mill is to be erected at the Great Eagle mine at Red Rock, which was recently acquired by Eastern capital. Frank Groh is in charge of construction.

STEEPLEROCK.—The Duncan Mining & Milling Co., which completed its new cyanide mill in July of this year and ran for some time on the ores of the district, has gone into the hands of a receiver.

COLUMBUS.—The Metals Exploration Co., of which O. Wiser is president, has purchased the Manning group of claims in the Tres Hermanas mountains, as well as adjoining claims owned by T. G. Lockland and others. Houses have been erected, an engine, hoist, and compressor are on the ground, and development has been started.

PINOS ALTOS.—The Calumet-New Mexico concentrator south of Pinos Altos is again operating on ores from the Manhattan mine. Ore shipments from Lordsburg for October were 80 cars of an approximate gross value of \$70,000.

UTAH

FREIGHT-RATES REDUCED.—NEW WORK PLANNED AT SILVER KING CONSOLIDATED.

SALT LAKE CITY.—Freight-tariffs will be published during December by the Salt Lake Route and Western Pacific railroads announcing reductions in rates on certain classes of ores. The Salt Lake Route will reduce the rate on ores up to \$15 per ton and the Western Pacific will reduce rates on ore valued at more than \$60 per ton. The reduction announced by the Salt Lake Route will benefit sundry shippers in Nevada who produce low-grade ore. The Western Pacific Railroad reductions will benefit Nevadan and Californian mines, served by its lines. Application has been filed with the State Land Board for the lease of 640 acres of land for the development of potash, alunite, and associate minerals. The section involved is in the mineral district just east of Marysville, in Piute county. The application was filed by Chicago and Indiana capitalists. The directors of the Cardiff Mining Co. have declared a dividend of 15c. per share, payable November 29. This is the only dividend declared this year and totals \$75,000. The grand total to date is \$875,000.

PARK CITY.—During the week ending November 20, the Judge properties shipped 590 tons of ore; Ontario, 511; Silver King Coalition, 394; and the Keystone, 110. The milling plant of the Glenallen Mining Co. is nearing completion and it is expected to be in operation by December 15. At the present time only development is going on in the mine, but as soon as the mill is finished a full force will be put on to supply the required tonnage of low-grade ore. At the Park-Utah property, the '15-4' fissure, which has been followed for more than 1000 ft., producing considerable second-grade ore, with occasional pockets of high-grade material, has recently opened a full face of first-class ore which has indications of developing into a large body.

Solon Spiro, president of the Silver King Consolidated Mining Co., recently returned from New York. When asked regarding conditions at the property, he stated that arrangements are being perfected to start two raises. A three-compartment raise will be put up on a series of

fissures just north of the large dike recently cut by Spiro tunnel, to the overlying limestone. Another raise will be put up on the body of iron ore, containing some gray copper, silver, and gold, opened up last month for a distance of 40 ft. at the side of the tunnel. Operations were suspended for a week at the Naildriver property, owing to trouble with the boiler-plant. Work in the mine is being done on the 500, 600, 700, and 900-ft. levels, according to J. D. Fisher, superintendent.

EUREKA.—T. H. Heal, president of the Greeley Mining Co., in the northern part of the district, visited the property recently with Charles Zabriskie, mining engineer of Salt Lake City. Mr. Heal states that the visit was for the purpose of selecting a shaft-site and that it is the intention of the company to commence sinking at once. There has been little activity in the northern part of this district for some time, and mining men familiar with the ground believe the Greeley to be a property of exceptional promise. Shipments from this district for the week ending November 19 totaled 153 cars, of which the Tintic Standard shipped 38; Chief Consolidated, 37; Dragon, 17; Eagle & Blue Bell, 13; Grand Central, 8; Mammoth, 7; Iron Blossom, 6; Victoria, 5; Iron King, 5; Gemini, 4; Swansea, 4; Centennial Eureka, 2; Bullion Beck, 2; Eureka Hill, 1; Gold Chain, 1; Sunbeam, 1; and Colorado, 1.

At the Zuma property, work is being carried on in two places. A drift to the south-east from the bottom of a 75-ft. winze was started recently, and a streak of high-grade ore has been cut. On the 800-ft. level, a drift is being sent to the south. Recently the main shaft has been re-timbered. An assessment of one cent per share, for the purpose of carrying on development, has been levied, delinquent December 20, with sales-date January 11. At the Little May property, adjoining the South Standard, a 4-in. streak of gray copper has been opened on the 190-ft. level. Within five feet it has widened to 14 in. An average sample gave returns of 13% copper and 4 oz. silver per ton, according to John Matson, the president of the company.

The Tintic Standard Mining Co. has awarded a contract for the erection of additional dwellings and lodging-houses at its mine in the eastern part of the district. Excellent progress is being made on the concentrating plant being erected on Warm creek; it will be ready for operation soon after the first of the year. The Mammoth Mining Co. has entered into a temporary arrangement with the A. S. & R. Co., which will permit the resumption of mining copper ores. It is expected that a similar arrangement will be made that will enable the company to resume shipping from its mill-dump.

OGDEN.—Encouraging developments are reported from the property of the Southern Pacific Gold & Copper Mining Co., in the Sierra Madre district, 10 miles north of here, according to H. A. Strauss, manager. The floor of the shaft now shows about six feet of excellent mineralization, averaging \$3 in gold, 1.2 oz. in silver, and 17.58% copper. Within another 20 ft. of drifting, it is thought the contact will be reached.

BRITISH COLUMBIA

SILVER STANDARD MINE IS SHUT-DOWN.—BRITANNIA TEMPORARILY SUSPENDS PRODUCTION.

VANCOUVER.—The Coast Range Steel, Ltd., has been incorporated with a capital of \$15,000,000 for the purpose of erecting an iron and steel plant in British Columbia. Arrangement has been made with the government of British Columbia for a bounty of \$3 per ton of iron produced from British Columbia ore during the first three years of the plant's operation. An effort is being made to induce the Federal government to permit machinery for the plant to be imported duty-free. The provisional directors are: H. J. Landahl, F. T. Congdon, J. D. Kearns, and Montague Moore, of Vancouver, and

Last year, the Britannia was the only copper mine in the Province to show an increased production, the output for the year being greater than in any previous year. During the year 640,000 tons of ore was mined, 615,000 tons milled, 17,250,000 lb. of copper, 98,600 oz. of silver, and 4200 oz. of gold were produced. Development work will be continued, but unless production is re-started by the beginning of the year it is probable that more men will have to be removed from the payroll.

PRINCE RUPERT.—Owing to the marked decline in prices of lead and zinc, the Silver Standard mine, at New Hazelton, is to be closed entirely. It had been intended to continue the development of the mine and shut-down only the mill. Recent discoveries of gold-silver-

SOUTH HECLA MINE AT ALTA, UTAH

John Steta, of New York. Other mining companies that have been incorporated recently are: The Soda Mining & Products, Ltd., \$75,000; Alice Arm Holdings, Ltd., \$1,000,000; Crescent Oil Holding Co., Ltd., \$175,000.

The Britannia Mining & Smelting Co. has discontinued production and will not ship any concentrate to the Tacoma smelter until either the price of copper advances or working conditions allow of the production of copper at a reasonable profit at present prices. Under ordinary conditions the Britannia employs between 600 and 700 men. About 250 men have been discharged, and these have come into the city, where already there are many unemployed men, notwithstanding approaching election time, when it is the custom for the party in power to 'make' temporary jobs with the view to gaining votes.

copper ore, with gold predominating, on Princess Royal island, have caused considerable local excitement, and it is likely that much development work will be done on the island next year. The formation is said to resemble that found at the Surf Inlet mine.

TRAIL.—F. H. Jackson, of Rossland, and Denver associates have purchased the White Swan group, at Burnt Basin. Development of the property will be started next spring. The ore received during the second week in November at the smelter totaled 8187 tons, of which the Consolidated M. & S. Co. mines were responsible for 7527 tons. The United mine, at Ainsworth, appeared on the list for the first time this season. The Associated Eastern B. C. Boards of Trade have petitioned the Federal government for an investigation into the prices of

coal and coke and have asked for a revision in the freight-rate for coke. It was decided, too, to hold the next annual mining convention at Grand Forks.

AINSWORTH.—Thomas and Joseph Haws, George McPherson, Glen McLeod, and E. and D. McLennan have taken a lease of the No. 1 mine from the Consolidated M. & S. Co. The mine has been a good producer and is well equipped. Last year it produced 235 tons and this year, to date, it has produced 336 tons of high-grade ore. There is a tramway from the mine to the landing at Cedar Creek and a wagon-road to Ainsworth, eight miles away.

ONTARIO

CHAMBERS-FERLAND FINDS HIGH-GRADE ORE.—HOLLINGER HAS INCREASED WORKING FORCE.

COBALT.—The Mining Corporation, which is the largest individual power consumer in the Cobalt field, has reduced its consumption to the extent of about 700 hp. This step, together with somewhat similar action as some of the other mines, including complete curtailment at the Beaver Consolidated, has relieved the power shortage.

Working under a leasing arrangement through a shaft on the Right of Way Mines, the Chambers-Ferland has extended a cross-cut 150 ft. into its own property and has made an important discovery of silver ore. At the point where the find has been made, the cross-cut lies in a layer of slate. Over a width of $4\frac{1}{2}$ ft. the average silver content is $28\frac{1}{2}$ oz. per ton, while the lowest assay across 22 ft. is $5\frac{1}{2}$ oz. The conglomerate formation is estimated to lie about ten feet below the cross-cut, and with such silver minerals shot up into the usually unproductive slate, the conglomerate is likely to contain a high-grade deposit. This is the official declaration based upon former results in the Chambers-Ferland.

Press dispatches convey the intimation that the Ontario government is considering a plan to relieve any hardship which may have been caused by the application of an Order-in-Council of October 13 which declared all patented mining claims in Ontario forfeited to the Crown, on which a certain Provincial tax of \$2 per claim had not been paid. Various holders declare they received no notice, and knew nothing concerning the tax until informed that their ground had been re-located.

Dividends paid during the current year by silver and gold mining companies in the district of Temiskaming exceed \$7,000,000. This represents an increase of over \$600,000 over the 1919 record. The increase was due to the Dome Mines at Porcupine having resumed interim disbursements at the rate of 2% at intervals of every three months, as well as to the Hollinger having paid two extra dividends of 1% each.

T. E. Godson, mining commissioner, heard the case this week in which prospectors who re-staked the Kirkland-Hudson mine entered claim for \$20,000. The defence was based upon the special Order-in-Council passed by the Ontario government which relieved the property from forfeiture prior to the hour set for such a penalty. It was considered this Order precluded any right the pros-

pector might have had to re-stake the mine. Decision has been reserved.

PORCUPINE.—Labor conditions having considerably improved, the Hollinger Consolidated has latterly been able to increase the scope of its operations. The company has declared another dividend of 1% payable December 1 bringing its total disbursements for the year up to \$1,968,000, as compared with \$1,722,000 in 1919. The favorable outlook indicated has resulted in an upward movement on the stock exchange. Development work at the Dome Mines has also been greatly stimulated by the recent addition to its working forces, but the break-down of a large underground crusher, which it will take some time to repair, is causing serious inconvenience. J. P. Bickell, president of the McIntyre-Porcupine, which, in conjunction with the Temiskaming, of Cobalt, recently purchased the Blue Diamond and Canadian Coalfields coal mines of Alberta, has returned from a visit to these properties and states that excellent progress is being made with their development. New machinery is being installed as rapidly as possible and the output has already been increased 50% now amounting to 700 tons daily. Operations have been put upon a profitable basis much earlier than was expected.

MEXICO

DENOUNCEMENT OF MINERAL LANDS IN CHIHUAHUA AND DURANGO IS ACTIVE.

TORREON.—Something like the pre-revolution activity in filing upon mining claims in the States of Chihuahua and Durango is being resumed. Many of the denouncements, as these applications are called, are by Americans. Prospectors who were kept out of the mineral district of Mexico for several years on account of the revolution and bandit troubles are now returning in large numbers. Advices have reached here that a group of twenty-nine claims has been filed upon in the Velardena district during the last few days. These claims are to be developed extensively, it is stated, and if ore is discovered it will be sent to the smelter of the American Smelting & Refining Co. at Velardena. In the San Dimas district of Durango, E. H. Townsend has taken up several claims, from which he expects to produce soon. There are several rich mining districts in Durango that are remotely situated from railroad transportation, San Dimas being one of these. Another district that promises to undergo rapid mining development, now that the era of disturbances has passed, is Santiago Papasquiaro, which is rich in gold, silver, and lead ores. Joseph E. Trumbley has just filed on 22 claims in that district and will start development as soon as machinery and equipment can be installed. Ore-shipments from the various districts show a gradual increase, due to the improvement in railroad transportation. Much new machinery is now coming into the country for installation in mines. Special attention is being given to re-timbering many of the mines, and the timbers for this purpose are shipped from the United States.

THE MINING SUMMARY

ARIZONA

Globe.—It is reported that drilling to a depth of 3000 ft. on the Castle Dome property has indicated a deposit of 1.4% copper sulphide ore that is capped with 20 ft. of 2½% oxidized copper ore. Work has been suspended till spring.—Drilling of 600 acres is to be started on the Warrior Copper Co.'s property in Lost gulch with three drills. This area adjoins the Louis D'Or property. Considerable ore has already been developed by tunnels. Last year the Superior & Boston Copper Co. shipped ore to the value of \$200,000 to the smelters at Miami and El Paso. Three copper-silver veins are being developed. T. R. Drummond is in charge of the work.

Grand Canyon.—The Northern Arizona Lead & Zinc Co. is working a small force of men at its mine near Catarack canyon. A considerable amount of vanadium ore, as desclizite and vanadinite, was developed in the mine a few years ago.

Kingman.—The shaft of the I.X.L. mine at Stockton hill is nearing the 350-ft. level at which point a station is to be cut and drifting on the vein commenced. The orebody at the 250-ft. level has proved to be high-grade shipping ore. The shaft will be sunk to the 500-ft. level. Complete plant for carrying on this work was recently installed and at present a large camp is under construction. G. D. Atlee is in charge of operations.—Regular shipments are now being made from the Golden Star property at Mineral Park. It is announced that a car of ore will be shipped every week or 10 days, the first car recently shipped having proved so satisfactory. The ore is high-grade silver-gold ore. Development work is being pushed and a large tonnage of milling ore is being opened apart from that which is being shipped. The drift on the 185-ft. level of the new shaft has proved the vein to be large. George Willeston is superintendent.—The main shaft of the C. O. D. mine is nearing the 500-ft. level. Recent reports state that both drifts on the 400-ft. level are in high-grade shipping ore. Construction of the mill is progressing rapidly. The new road to the top of the hill has been completed and is stated to be an excellent road.

Miami.—It is reported that the American Asbestos Association, whose property is situated at Chrysotile, 40 miles north of Globe on Ash creek, is producing 1½ to 2 tons of sorted crude asbestos daily which is transported to Rice on motor-trucks and shipped to the mills in the East.

CALIFORNIA

Nevada County.—Announcement of the discovery of a rich vein in the South Star mine, in the Deadman's Flat district, is made by A. W. Johnson, manager for the company. A lode from three to four feet wide and running high in gold has been uncovered at a depth of 105 ft. and the prospects of developing a large ore-shoot are good.

Shasta County.—The Mammoth Copper Co., a subsidiary of the United States Smelting, Refining & Mining Co., has increased its holdings on the Shasta copper-belt by acquisition of the Crystal group of 24 claims under a two-year option. The Crystal property lies north of the Balaklala mines and west of the Vulcan property, and has been under-

going development for several years. The transaction is in line with the policy of the Mammoth company to gather in copper properties adjacent to its holdings in the Kennett district to ensue a steady supply of ore for its smelter.

Stanislaus County.—The big dredge which was launched a few weeks ago by the Yankee Hill Gold Mining Co. has commenced operations in the Stanislaus river between Oakdale and Knight's Ferry. The Pacific Gas & Electric Co. has connected the 200-hp. motor which will drive the machinery, and within a few weeks it will be known whether or not the investment of nearly \$200,000 will be repaid from the gold in the channel of the Stanislaus river. The company has under lease about ten miles of the river-channel.

Tuolumne.—The Harvard mine, together with a large number of outlying claims, has been sold to John Ferguson and associates of Berkeley. The transaction includes the ten-stamp mill on the Capp-Mussel group and equipment owned by the Harvard company. While no formal announcement has been made, it is understood the new owners plan to develop the property in 1921. The Harvard long ranked among the premier producers of the Mother Lode, but has been idle several years.

IDAHO

Coeur d'Alene.—Ivan de Laschmutt, manager of the Standard Silver-Lead company's mine at Silverton, B. C., was elected chairman of the Columbia Section of the A. I. M. & M. E. at the session held at Kellogg on November 19 and 20. The following papers were presented at the meeting attended by 147 members: 'The Federal Income Tax and Mine Valuation', by W. Earl Greenough; 'Precipitation of Smelter-Fumes in Series-Treatment at the Bunker Hill Smelter', by J. P. Schuttenhelm; 'Hydraulic Classification and Table-Riffing at the Bunker Hill Concentrator', by C. Y. Garber; 'Considerations in Relation to Flotation', by Thomas M. Owens; 'Mechanical Shoveling in the Bunker Hill Mine', by William McDougall; 'Electrical Drying of Flotation Concentrates', by W. C. Clark; 'Treatment of Complex Zinc-Lead-Silver Ores of the Coeur d'Alene District', by W. G. Woolf. The papers by Mr. Schuttenhelm, Mr. Garber, Mr. McDougall, and Mr. Clark were amplified by slide views which added much to their value. Following the formal papers J. B. Parker, formerly in charge of the flotation plant at the Interstate-Callahan mill, but now at the Bunker Hill, discussed selective flotation as applied to zinc and lead, using a blackboard to illustrate the process.

The Western Union mine, situated two miles from Wallace, has 50 tons of high-grade ore ready to be sent to the Bunker Hill smelter. A new stope was opened recently which showed a foot of lead-silver ore. Ben L. Collins, of Spokane, is manager of the property.—The Hecla Mining Co. will disburse its regular quarterly dividend of \$150,000 December 28. The payment will be at the rate of 15c. per share. It will increase the disbursements for the year to \$650,000 and the grand total of \$8,505,000. An extra dividend of \$50,000 was disbursed in the second quarter. Ore has been developed to a depth of 2000 ft. in the main vein. The body is 16 ft. wide and has been followed by drift for 500 ft. or more. This body has a length of 1600 ft. on the 1600-ft. level. A streak of high-grade lead-silver ore five feet wide

is being developed at the face. The company recently acquired the Russell and Mono claims and the Tiger-Poorman group from the Federal Mining & Smelting Co. for \$750,000.

Idaho County.—The Orogrande Gold Mining Co., owner of mining property near here, has completed the erection of a building and will equip a mill with a capacity of 500 tons daily, according to M. A. Sherman, vice-president. A roaster and tanks are in process of construction. The parts to be bought will be installed in time to begin operations in the spring. The plant was equipped several years ago to dress oxidized ore. The equipment being installed is designed to recover the gold in the sulphide ore. It includes leaching tanks, roaster, ball-mill, and Wilfley tables. The mine is developed and ready to yield ore.

MISSOURI

Joplin.—While the present low price for zinc ore has resulted in a curtailment of output in practically all of the mines of the district, the mines of the Eagle-Picher Lead Co. are doing all the reconstruction and repair work possible in order to give jobs to their employees oldest in point of service. Out of seven properties owned by the company, normally employing about 1500 miners, four mills are operating, namely, the Netta, Bingham, Crawfish, and Swift. The Perrin mill is being dismantled and removed to shafts No. 25 and 26 in Kansas, about 1½ miles north of the former site, where it will be known as the Bendelari mill. A drift is being made to connect shaft No. 24, near the south-west terminal station with shaft No. 20 at the Whitebird mill, where the 'dirt' will be milled. On November 20 the wages of shovelers were cut from 12½ to 11c. per can. The wages of other underground workers were unchanged.

Otis White has opened a body of zinc ore at the Buffalo mine north-west of Picher. The cave is several hundred feet long and many feet in width and is filled with the finest of 'resin jack' in chunks varying from a foot to four or five feet in diameter. The chunks will run from 45 to 50% zinc sulphide. The first day's mill-work on stuff from the cave resulted in the making of 59 cars of zinc and 4 cars of lead concentrate. The opening of the cave created something of a sensation in the neighborhood and hundreds of visitors have viewed the underground wonder, among them being many mining men of the district. The Sullivan mine at Commerce, owned by White, suffered the loss of its mill by fire one day last week. The loss was considerable, but White has not been worrying about that since he has made the big find at the Buffalo mine.

WASHINGTON

Spokane.—The American Refractories Co., operating a magnesite mine, near Valley, 50 miles north of here, has more than doubled the capacity of its truck-lines hauling the calcined product to the railroad. Eleven heavy trucks are being worked 24 hours per day. Considerable time and money has been spent in putting the roads into condition for hauling, so that trucks may run as late as possible into the season.

Obituary

Alex Shields, a prominent mining man of Hamilton mining district, White Pine county, Nevada, died on November 24 in San Francisco. He had resided at Hamilton for about 40 years. He was manager of the Ne Plus Ultra mine, which position he had held for 15 years.

Isaac E. Hadley, 69 years of age, for the past 25 years being general foreman of the American Smelting & Refining Co.'s silver-lead smelter at Murray, Utah, died on November 21. He had been a resident of Utah for 28 years, and had been connected with the smelting industry throughout that period. He is survived by his wife and four children.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

R. C. Gemmell was in San Francisco last week.

James E. Babcock, of Los Angeles, has been at Marysville, Utah.

Ira B. Joralemon has returned from Mexico to Bisbee, Arizona.

H. R. Chartran, of Paris, is in San Francisco on his return from Siberia.

J. Morgan Clements, on his return from Mongolia, has gone to Hinar, near Canton.

D. J. Argall, of Thane, Alaska, is spending the month of December at San Diego, California.

W. J. Loring, after attending the American Mining Congress at Denver, went to Washington.

Edwin Mills and J. F. Manning have been examining the Mongolor mine, near Urga, in Mongolia.

E. A. Cappelen Smith has been awarded the gold medal of the Mining and Metallurgical Society of America.

H. Hardy Smith is expected in San Francisco before the end of the year on his return from London to Australia.

Robert Linton, president of the North Butte Mining Co., was in San Francisco on his way from Montana to New York.

J. Malcolm MacLaren has been appointed a member of the technical committee of the National Mining Corporation in London.

A. G. Burritt, of Salt Lake City, has been making an examination of the Eureka-Nevada mine, in New York canyon, Nevada.

F. Leslie Ransome attended the convention of the American Mining Congress at Denver, on his way to Oatman, Arizona.

Marshall D. Draper is now chief engineer to the Kutchiou Tin Trading Co. in Yunnan, China. T. K. Li is acting as his assistant.

Forest Rutherford has returned to New York, after spending several months in Colorado on mine examinations and milling problems.

A. W. Newberry, accompanied by C. A. Newton, sailed on November 27 from New York for Nicaragua, to examine the San Albino mine.

W. H. J. Brown, F. B. Kever, and Wallace Macgregor, of San Francisco, have been examining mining claims at Eureka, Nevada.

Rush T. Sill and Harley A. Sill have left for Arizona and New Mexico, where they will examine several properties, returning to Los Angeles about the first of the year.

C. S. T. Farish has resigned his position as general foreman for Backus & Johnston to accept the position of assistant mine superintendent with the Amparo Mining Co. at Etzatlan, Jalisco, Mexico.

A. W. Tucker, after sixteen months field-work for the Bureau of Mines in connection with War Minerals Relief claims, has resumed private practice in the Southern Appalachians, with an office at Salisbury, North Carolina.

H. Foster Bain was in San Francisco this week on his return from Shanghai to Washington. On November 30 he delivered an interesting address on his experiences in China before the Engineers Club.

C. M. Weld, mining engineer, D. M. Liddell, chemical engineer and metallurgist, and P. H. Lazenby, civil engineer with wide experience in public utilities, have formed a partnership for practice as consulting engineers and economists under the firm name of Weld, Liddell & Lazenby, with offices at 2 Rector street, New York.

THE METAL MARKET

METAL PRICES

San Francisco, November 30

Aluminum-dust, cents per pound	65
Antimony, cents per pound	7.50
Copper electrolytic, cents per pound	14.75
Lead, pig, cents per pound	6.00-7.00
Platinum, pure, per ounce	\$85
Platinum, 10% iridium, per ounce	\$125
Quicksilver, per flask of 75 lb.	\$55
Spelter, cents per pound	8.00
Zinc-dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

November 29.—Copper is inactive and weak. Lead is stagnant and lower. Zinc is dull and declining.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

IMPORTING GOLD FROM LONDON

Kuhn, Loeb & Co. have imported nearly \$65,000,000 gold this year, bought in the London open market. This is 'brand new' gold—not like that brought over recently by reserve banks, which was 'ear-marked' to their credit in Bank of England and which they already counted in reserves. Although this \$65,000,000 is a private importation, most of it has gone to the New York Federal Reserve bank, and through it, into the reserve system, because Kuhn, Loeb & Co. have been selling the metal directly to the reserve institution. The importers have found this a more advantageous way of handling incoming gold. It has often meant dollars and cents to them. Both parties profit, since the reserve bank is placed in immediate position to expand credit.

While importers can get immediate credit under certain conditions by turning their gold into the Assay Office, the Government institution is not in position to render the same facilities as the reserve bank. For instance, Kuhn, Loeb & Co. have found that if a consignment of gold comes into their possession after 2:30 p.m., the Assay Office will not give them credit for the amount until the following day. Federal Reserve Bank will give them credit therefor up to a late hour in the day. On gold consignments involving several millions, the saving of a day's interest is no small consideration.

In this way the more up-to-date management of the Federal Reserve Bank, as compared with the red tape of the Government institution, is enabling the former to accumulate the yellow metal more rapidly than it would in ordinary course. The \$65,000,000 gold obtained by Kuhn, Loeb & Co. this year has been a pure exchange operation, based on position of sterling in this market. The gold is product of the mines sold in the open market. Bankers cannot get gold from the Bank of England, and there is an embargo on British gold exports. But the British government has made special exemption in case of gold from the mines currently offered in the open market. This may be taken by the highest bidder, and because of the low position of New York exchange and the exchanges at certain other centres, a high premium on the market gold has ruled. At present bar-gold in London is quoted at about 118s. per ounce, compared with about 85s. normal. Formerly India and the Far East were active competitors with New York, but now New York appears to be the only bidder, after Government requirements are filled. The British Indian treasuries are always given precedent.

It is commented upon that Kuhn, Loeb & Co. should be the only New York banking house importing gold from London at present. The distinction lies less with Kuhn, Loeb & Co. than with Rothschild & Co., London, who do the actual buying and who appear especially favored in this respect. Kuhn, Loeb & Co. are merely consignees of the metal sent by Rothschild & Co. Initial deposit of the gold at reserve bank, on basis of 40% reserve, would allow for note expansion of about \$160,000,000; but through ramifications of banking credit, potential credit expansion is in proportion of at least 10 to 1. Therefore Kuhn, Loeb & Co. importations have provided for a possible credit expansion of between \$600,000,000 and \$700,000,000.

MONEY AND EXCHANGE

Foreign quotations on November 30 are as follows:

Sterling, dollars:	Cable	3.50
	Demand	3.50%
France, cents:	Cable	6.13
	Demand	6.14
Lire, cents:	Demand	3.70
Marks, cents:		1.50

Eastern Metal Market

New York, November 24.

Liquidation in practically all the markets continues and quotations are lower.

Demand for copper has not improved. Further offerings have depressed values to new low levels.

There is no animation in the tin market, the tone of which is easy with prices lower.

Lead is freely offered in quantity and quotations are considerably lower.

Stagnation features the zinc market, with buying and production curtailed.

Antimony joins the procession and is also lower.

IRON AND STEEL

The Steel Corporation's announcement that it would not advance its prices unless "altered conditions" made advances necessary has had no measurable effect on the steel market, and its precise intent is not yet clear, according to 'The Iron Age'. It has been understood that the corporation seriously considered advancing rail-prices, and the fact that it made large contracts for 1921 into which the price was to be written later pointed to a higher level than \$47, which it has maintained since March 1919. Several independent mills that for more than a year have charged \$55 and higher for rails have refused to book orders for 1921 with the proviso that the Steel Corporation prices govern, and some of these mills could not meet the Steel Corporation's price without a drastic readjustment of wages.

Current export trade in iron and steel is about one-third the volume of a few months ago. One sale of the week was of 5000 tons of structural steel to the Dutch government, made by the Steel Corporation, the price being close to 2.65c., Pittsburgh, or about \$4 per ton higher than the basis for domestic business.

COPPER

The market does not improve; it goes from bad to worse, if anything, so far as prices are concerned. Consumers are still apathetic so far as large purchases are involved. There continue to be offerings by small producers and second-hands which have further depressed prices, caused by the necessity to convert metal into cash. It is understood that one or two large interests are willing to shade the 14.75c. price of the leading producers who have not thus far changed their asking price. The result of these conditions has been a recession in values to not higher than 14.50c., New York, for electrolytic copper at which level it is believed nothing less than sizable tonnages can now be obtained. For small lots from second-hands and small producers it is stated that 14.25c. can be done. We quote the market at 14.50c. for this year and 14.75 to 15c. for first quarter. When the market had receded to around 15c. a short time ago, fairly large sales were made at 15c. and 15.25c. for early and first-quarter delivery. Sales for foreign account are about the same, that is, light.

TIN

In a dull and uninteresting market the sharp slump in London on Monday of this week has been the only feature. Despite the fact that it was big, it was not followed by sellers on this side, because they regarded it as overdone or far-fetched. As a result the market here was not affected much but remained on Monday at 36c., New York, nominal, for spot Straits, or where it closed last Friday. On Monday, prices broke to £231 for spot standard, to £234 for future standard, and to £231 10s. for spot Straits, remaining yesterday, Tuesday, at practically those levels or £230 15s., £234 15s., and £231 5s., respectively. Yesterday spot Straits, New York, was again nominal but a little higher at

37c. Last week Thursday, November 18, was the only day of any trading and it was small. A little spot Straits changed hands at 37.25c. and some metal ex-steamer in the harbor at 37c. More was offered but there was no buying and competition was active for the business offered. Sales on the New York Metal Exchange in the week totaled about 75 tons, some October-November shipment going at 37.50 to 37.75c., and one 25-ton lot of Straits under the rule at 37.25c. Arrivals thus far this month have been 2580 tons with 3500 tons reported afloat.

LEAD

Late Monday another cut was made by the American Smelting & Refining Co. of 1/4c., reducing its price to 6c. both New York and St. Louis. Just previous to this the outside market had reached the 6c. level. The market may be termed as very weak, bordering on demoralization. While 6c. is the quotation it is hinted that inquiries involving large quantities could bring a lower price. These are free offerings of the metal in large quantities and the falling off in consumption is drastic and pointed to as the cause of the present tendency of the market. Because the low price in London and the possibility of imports, the New York price of the leading interest is the same as at St. Louis. At present value of exchange, the metal in London has a value of around 4.55c. per pound.

ZINC

The market has not improved but quotations have declined. Prime Western for early delivery is quoted at 6c., St. Louis, or 6.40 to 6.50c., New York, but demand is almost nothing. Galvanizers seem well supplied in relation to their orders for sheets and are buying only what they need here and there. There has been a slump in brass operations. The offerings of zinc come from interests needing the cash and from those operators who are working off ore piles or old stocks. The tendency to curtail output is marked. It is intimated that the industry as a whole is operating well under 50% of capacity with some producers down to a basis of 25% capacity.

ANTIMONY

Demand is light and unsatisfactory and carload or wholesale lots for spot or early delivery can be obtained at 5.87 1/2c., New York, duty paid.

ALUMINUM

Virgin metal, 98 to 99%, is unchanged at 32.90c. f.o.b. producer's plant from the leading interest, but other sellers are quoting 27.50 to 28.50c., New York, for wholesale lots for early delivery.

ORES

Tungsten: There has been no test of the market. Prices are therefore nominal at \$4 per unit for Chinese ore and \$5 per unit for Bolivian.

Ferro-tungsten is quoted unchanged at 90c. per pound of contained tungsten in guaranteed lump and at 70c. not guaranteed. The powdered form is quoted at 78 to 85 cents.

Molybdenum: Quotations continue normal with sellers' ideas at 60c. per pound of MoS₂ in regular concentrate and buyers' ideas of values at 50 cents.

Manganese: The market for high-grade ore is dead with quotations nominal at 45 to 50c. per unit, seaboard.

Manganese-Iron Alloys: American makers of ferro-manganese have reduced their asking price to \$150, freight allowed, which compares with \$170, basis, seaboard, formerly. The British price is still \$170, seaboard, but the development of any business could probably bring down this price. Spiegeleisen, 20%, is easier at \$62.50, furnace, but there is no demand.

Book Reviews

Elements of Descriptive Geometry. By George F. Blessing and Lewis F. Darling. 200 pp., ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

The material for this book was prepared in the main while the authors were teaching machine design at Cornell University, and the book is designed for, and arranged as, a class textbook. No human power could make the subject of descriptive geometry anything but difficult for the average student to grasp, but the authors appear to have done as well as possible under the circumstances.

Gold. Its Place in the Economy of Mankind. By Benjamin White. 128 pp., ill., index. Sir Isaac Pitman & Sons, Ltd., New York and London. For sale by 'Mining and Scientific Press'. Price, \$1.

This is one of fifty small books that describe the manufacture and use of every-day commodities, including, for instance, soap, tobacco, copper, and automobiles. The first chapter is captioned, 'Its Appreciation, Ancient and Modern'. Then come several chapters on production, use in coinage, and movement of gold over the world. A final chapter, 'Gold and the Great War', gives an excellent resume of the financial difficulties brought about by the War and clearly states some of the problems of 'gold currency-reserves'. It is a good popular book.

Geology of the Non-Metallic Deposits Other Than Silicates. Vol. I. Principles of Salt Deposition. By Amadeus W. Grabau. 435 pp., ill. Published by the McGraw-Hill Book Co., New York. For sale by the 'Mining and Scientific Press'. Price, \$5.

"This book," says the author in his preface, "is essentially a treatise on applied stratigraphy." It is a handbook on the geology of salts, using the term in its broad sense, to include nitrates, phosphates, borates, and similar deposits, that is, non-metallic minerals used in human industry. It starts with a chapter on the chemical principles underlying the methods by which such deposits are formed, and classifies them. Then follows the characterization of minerals and an account of their distribution in nature. The author is recognized as an authority on the subject; he is a scholar and writes clearly. The book should prove useful and welcome.

Political and Commercial Geology and the World's Mineral Resources. By J. E. Spurr. 544 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$5.

The purpose of this book is "to shed light upon the vast importance of commercial control of raw material" to governments. Commencing with petroleum, coal, and iron, the useful minerals are considered in successive chapters from the following points of view: uses, geological and geographical distribution, political control, and commercial control. One group includes the metals used as alloys for hardening and toughening steel; a second group includes the major metals other than iron, as well as some important non-metallic minerals such as magnesite, graphite, and asbestos; the third is that of the fertilizer minerals; and the last deals with precious metals, which in the final analyses are not so important as the others from the standpoint of national safety—which is in fact the motive for a careful study of mineral resources of the world. Each chapter is handled by a specialist and each summarizes the present-day knowledge regarding the distribution and utility of a particular mineral. Mr. Spurr concludes the book with a chapter, 'Who

Owens the Earth?' which gives the salient features of the separate chapters. The book is interesting; it is instructive.

Laboratory Manual of Testing Materials. By William Kendrick Hatt and H. H. Scofield. Second edition. 169 pp., ill., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The first edition of this book appeared seven years ago. The principal changes in the second edition are in bringing the material up to date, particularly the division relating to cement and concrete. The authors are both professors of civil engineering, one at Purdue, and the other at Cornell University. The book includes a general discussion of testing-methods, a description of the various types of testing-machines, and directions for performing the principal kinds of physical tests on the more important engineering materials. There is also an appendix containing skeleton specifications for various materials, and directions for making metallographic examinations.

American Lubricants. By L. B. Lockhart. 330 pp., ill., index. The Chemical Publishing Co., Easton, Pennsylvania. For sale by 'Mining and Scientific Press'. Price, \$4.

As the title-page states, this book is written from the standpoint of the consumer and deals with the use and the analysis of lubricants, and only incidentally with their manufacture. After a brief discussion of the production and refining of petroleum, the subject of friction and lubrication is considered. Then come several chapters each dealing with the lubrication of some particular kind of machinery. Physical and chemical tests for lubricating oils and greases are then discussed. The next two chapters are devoted to animal and vegetal oils and the testing of the same. Then come several chapters each dealing with specifications for some particular kind of lubricating oil or grease. The last forty pages of the book are devoted to specifications and tests for other petroleum products than lubricants. The purchaser or the user of lubricating oils will find much that is useful in the book.

The Mineral Industry, 1919. Vol. XXVIII. Edited by G. A. Roush. 902 pp., index. McGraw-Hill Book Co., Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$10.

This twenty-eighth volume of 'Mineral Industry' lives up to the standard established by its predecessors. The book is designed as a permanent and compact record of the year's progress in mining and metallurgy; it comprehends three distinct phases of the industry, namely, statistics of production, progress in technology, and the market or commercial features. The statistics are important but they are not the only valuable part of the work. Each section is in charge of an editor who is a specialist in the production of the particular commodity being discussed, so that the material presented is verified as far as possible by one who is an authority on the subject. The scope of the book is international, yet it is primarily an American product and most of the data deals with American production. Sources of information are the U. S. Geological Survey, the U. S. Bureau of Mines, and the Department of Commerce; the technical journals of this country and others; and to some extent private communications. No attempt has been made to include all minerals; indeed it may be that, in the opinion of some, the space devoted to some of the less important products could to advantage be used in greater elaboration of the technical discussion of the more prominent metals. The book is full of information that cannot be found elsewhere without an amount of searching disproportionate to the cost of this volume; it is an invaluable book of reference with the rare merit of being as nearly up to date as is reasonably possible.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

MOTOR-TRUCKS V. HORSES

In discussing the question of horse-haulage v. motor-truck, W. A. Carpenter, of the Acme Motor Truck Co., Cadillac, Michigan, says: While much has been said upon this subject, the following comparison will illustrate in a striking way the difference between the two methods, and may present the matter in a different light from that in which you have seen it before.

The average two-horse team will haul two tons over the average road, at a speed not greater than three miles per hour. Allowing one hour for the noonday stop, and another hour for loading, unloading, resting on grades, and miscellaneous delays, it is safe to say that the team will in a ten-day cover not more than 24 miles.

Now for the truck's side: No preliminary work in the morning is necessary, with the exception of a few moments inspection every morning, desirable in any piece of machinery. Allow the same two hours lost time each day for truck as allowed for team, though the hour allowed for such delays will be confined to loading and the greater part of this time eliminated. At the close of the first day the truck will be 136 miles from place of starting (remember the team has made but 24 miles). At the close of 300 days, truck will be 40,800 miles from the starting point, though during the 300 days the team has covered only 7200 miles. In other words the truck has carried two tons 33,600 miles farther than the team did in the same length of time. Keep this up for say five years, if the horses are able to work steadily 300 days per year for five years, and we find the truck 168,000 miles ahead of the team. Counting feed, care and up-keep of team, harness and wagon, the cost of operation and maintenance is about the same for truck as for team, at least not much more. The investment, of course, is much greater with the truck than with team, but as will be seen from above, the results do not compare favorably to the horse.

ANNUAL DRILLING CONTEST AT BAXTER SPRINGS

Down in Baxter Springs, Kansas, in the Joplin district, the feature of the annual fall festival is a rock-drilling contest. The contest was held this year on October 20. Teams are required by the rules of this contest to set up tripods; connect hose to drill; drill hole clear through rock; tear down drill; disconnect hose; loosen bolts; and place hose, steel, drill, and tripod back in position where found.

The rock used last year was a block of Carthage marble five feet square, marked off into 12 square spaces, one space being reserved for each drilling team, while this year a block of concrete six feet thick and filled with boulders, was used. Miles and Vickery, who carried off the first prize last year with the Waugh turbo drill, were just one second behind Abbott and Mitchell, the team that won the first prize this year. Both teams operated the Waugh turbo drill, as did also Santon and Cox, winners of the third prize in this year's contest.

The drilling time for the first three teams including setting-up, tearing-down, etc., was as follows: first, 4 min. 26½ sec.; second, 4 min. 27½ sec.; third, 5 min. 4½ sec. The nearest competitor of the three winning teams, operating

another make of drill, completed their hole in 7 min. 4½ seconds. Last year the winning time in this contest was 5 min. 16 seconds.

COMMERCIAL PARAGRAPHS

Henry F. Pratt has been appointed mid-western sales-manager of the Taylor-Wharton Iron & Steel Co. and its subsidiaries, with offices at 502 Denham Bdg., Denver, Colorado.

A handsome new catalogue has just been issued by the Worthington Pump & Machinery Corporation illustrating and describing Worthington marine pumps and auxiliaries. The catalogue, No. BK-2000, consists of 125 pages of descriptive matter and illustrations, and those engaged in marine work generally will find it a comprehensive and useful publication. A copy can be obtained from the company's nearest branch office.

Bulletin No. 48704A, 'G-E Insulating Compounds', issued by the General Electric Company, presents the principal characteristics and effective adaptations of the wide field of electric insulating and coating materials. Imperative factors in selection are: electrical properties, dielectric strength, insulation resistance, breakdown resistance under high frequency or oscillatory discharge and temperature-change resistance; also physical properties, tensile or compressive strength, rigidity or flexibility and high or low heat-conductivity; and finally chemical properties, form and composition of the material. This is essentially a work of research and experience for which the extensive Research Laboratories and magnitude of activities of the company combine to perfect such products and their methods of utilization.

The Dodge Sales & Engineering Co., of Mishawaka, Indiana, announces the publication of a catalogue on 'Dodge Standardized Elevators and Conveyors'. The catalogue is one of the most comprehensive that has ever been issued covering the above subjects and should constitute a textbook. The complete tables of data incorporated in the catalogue represents an immense amount of work on the part of the Dodge Sales & Engineering Co. The tables used in this catalogue are based on maximum conditions for the different carrying parts, rather than on the assumption of conditions and the working out of a design for those particular conditions. An interesting feature is the simple manner in which designs involving gearing are developed, whereby almost any drive whether for a conveyor, elevator, or other speed reduction can be picked out of tables; pitches, numbers of teeth, and shaft sizes are likewise given. All details are thus solved without any complicated calculations. The catalogue is standard Dodge size, 6 by 9 in., and is printed on fine enamel stock paper, the whole containing 160 pages and about 150 illustrations. The catalogue has been in preparation for more than a year and a half and no pains or expense has been spared to make it comprehensive in every detail. The catalogue was prepared under the direction of A. O. Gates, of the Dodge Sales & Engineering Co., whose method of design of bucket-elevators has resulted in greatly improved elevator practice in plants in all parts of the world. According to present plans the new catalogue will be read for distribution on or about December 1.

SPEAKERS AND SPEECHES	826
How to curb excessive speaking at conventions. The kinds of people guilty of talking too much. Devices for stopping the nuisance. The ineffectiveness of chairman. Speeches at banquets and the effect of prohibition in checking exuberance.	

INDUSTRIAL RELATIONS	827
Comment on the letter by Dr. Corless and the articles by W. R. Ingalls. The book by Whiting Williams and the first-hand testimony that it gives upon the conditions under which men work in the steel and iron plants, as well as shops and foundries. The need for explaining a man's job to him. Comment on the letter from F. J. Bourne and deprecation of a warlike attitude on industrial relations.	

DISCUSSION

LABOR THE HOLDER OF THE NATION'S WEALTH	
By C. V. Corless.....	829
Mr. Corless dissents from some of the conclusions of W. R. Ingalls. The harsh attitude of superiority is dangerous. Division of income. The value of the directing mind. What capital really is. The responsibility of the engineer.	

THE HUMAN FACTOR IN MINE MANAGEMENT	
By F. J. Bourne.....	831
Mr. Lewisohn loses sight of the complexity of human nature. Trade-unionism must rebuild on a common-sense basis. The 'human-factor' plan has been tried and found wanting.	

ARTICLES

MINERALS SEPARATION'S POSITION UNDER THE PATENT LAWS AND THE ANTI-TRUST LAWS	
By Gilbert H. Montague.....	833
Constitutional provisions regarding patents. They	

must 'promote the progress of science and useful arts'. Precise limits of patent No. 835,120, and of the two subsequent patents under litigation. Occupied zone soon to be vacated. Stretching 17 years into eternity. Royalties, discriminatory and eternal. What the Trade Commission can accomplish. A seeming concession on the part of Minerals Separation is illusory because of the provision of the license preventing the licensee from disputing or objecting to any interpretation placed upon the patents by Minerals Separation.

PLATINUM

By S. Skowronski	840
Sources of platinum. Use in science and for jewelry. A by-product from the electrolytic refining of blister copper.	

MILLING PRACTICE AT THE BENGUET CONSOLIDATED MINE—II

By C. M. Eye and M. F. Dodd.....	841
Details of the operation of the mill. Stamping and classification. Details of tube-mill practice. Agitation and replacing in the Trent machine. Precipitation on zinc shavings. Cleaning-up and refining.

THE MARCY ROLLER MILL *An Engineering Product*

This mill carries 18 tons of rods or rollers, $3\frac{1}{2}$ -in. diameter and smaller. All crushing is done by rolling action.

In order to carry this rod mass effectively and economically, the best material and engineering design enters into the construction of the Marcy Roller Mill.

The particular MARCY ROLLER MILL illustrated above is designed for large and important installations. We recommend personal investigation as to its operation. Salesman's talk is one thing—personal investigation is another.

Write us and we will tell you where you or your representative will see these mills in operation.

THE MINE & SMELTER SUPPLY COMPANY

A Service Station Within Reach of You

DENVER

SALT LAKE CITY

EL PASO

New York Office: 42 Broadway

T. A. RICKARD, . . . Editor

ANYBODY who has traveled recently across country will appreciate the remark of the man who was asked, "How's the railroad situation?", and answered, "About the same. Congestion in the freight-cars and indigestion in the dining-cars". And what is worse, the price of the indigestion is piratically excessive.

EXTRAVAGANCE is indicated unmistakably by the fact that during the fiscal year 1920 the importation of diamonds into the United States was nearly double in value that of the previous year and more than three times the total in 1918. More than 90% of the imports came from South Africa, from the mines of Kimberley and the adjacent region.

REFERRING to the stimulation of gold mining, we note that the Governor of Western Australia speaks favorably of the prospecting done by returned soldiers. They have been aided by the Mines Department and the Repatriation Department, the result being an "unprecedented activity in prospecting throughout the eastern goldfields". Here is an obvious method for assisting our demobilized soldiers, if out of work. We suggested the plan more than a year ago.

AMONG recent statements that one may call "important, if true" is the announcement of an invention by Mr. William L. Emmet of the General Electric Company whereby he is enabled by means of a mercury-vapor boiler and turbine "to cut the cost of producing electric power and light in half". This invention is said to have been "perfected". The only change that need be made in existing plants is in boilers. It looks like a body-blow at H. C. L., for if the cost of power can be halved, the cost of manufacturing will be reduced greatly. We look forward to further information on the subject.

THE 'Financial Times', of London, remarks that there is nothing to justify the high premium at which Minerals Separation shares are quoted, namely, £10½ for the £1 shares. For the fiscal year just ended a dividend of 5 shillings has been distributed, as compared with 10 shillings in 1918 and 1917. However, our British contemporary says that "the market attaches much speculative interest to the company's new process". This is a process "for combining pulverized coal and oil in a stabilized form, which produces a valuable liquid fuel".

Minerals Separation owns the patent rights to this process all over the world except in Japan and the American continent. Japan does not grant patents, and the rights on the American continent, presumably, have been transferred to the Minerals Separation North American Corporation in New York.

A DISPATCH from Cananea states that the Cananea Consolidated Copper Company has posted notices announcing the suspension of all operations at its mines and smelter in Northern Sonora. This action will throw 2000 men out of work and will indirectly affect many more; indeed, an extremely large territory is dependent directly on the Cananea Consolidated enterprise. The reasons assigned are the long-standing threat of labor troubles and the burdensome taxes imposed by the Mexican government on the production of copper. The underlying reason obviously is the condition of the world's market for copper. It is stated that Señor Adolfo De la Huerta, former provisional President, has been designated by the Mexican government to undertake an adjustment of the difficulty. He has the reputation of being a fair man, and quick-witted; therefore we feel assured that he will recognize the importance at this time of bringing about a settlement that will be just to all concerned.

OUR friends in London are nothing if not consistent; despite the protests made from this side against the bestowal of the gold medal of the Institution of Mining and Metallurgy on Mr. H. L. Sulman, the same engineering society has gone out of its way to award to the same gentleman the gold medal and premium of the Consolidated Gold Fields of South Africa, namely, the medal and premium given annually by that well known company for bestowal by the Council of the Institution. We need not repeat the objection to this selection of Mr. Sulman for such honors at this time, when to the mining profession in the United States he is known only as the patentee and metallurgist identified with Minerals Separation, a corporation that has made itself extremely unpleasant to so many engaged in our mining industry. The award of this second medal, like the first, is "for his paper, 'A Contribution to the Study of Flotation'". In his letter to 'The Mining Magazine' of May last, Mr. Sulman stated that his partner, Mr. Hugh F. K. Picard, "had no part in the preparation of the paper nor in the research which led to its publication. Neither was he

co-author with me of the original notes referred to, for the sufficient fact of his absence from England during a large part of the time that the research was being conducted. It is true that during part of this time I had the benefit of his help, but he disclaims entirely co-authorship of the notes". Then Mr. Picard is unusually self-extinguishing, for we have before us as we write a copy, duly attested by a notary public, of the treatise mentioned, as submitted in the Miami litigation with Minerals Separation. On the cover it bears the following title: "'The Theory of Concentration Processes Involving Surface-Tension', by H. Livingstone Sulman, F.I.C., M.I.M.M., and Hugh Kirkpatrick Picard, A.R.S.M., M.I.M.M." Of course, those who award medals have a right to give them to whosoever they please, but in this case the second medal might, it seems to us, have been bestowed upon Mr. Picard. He is a good fellow and a first-class metallurgist, anyhow.

WE note a small item in an English paper, in which the writer condoles with the Cornish miners who have been discharged from their work in the tin mines; it is estimated that in all some 1300 men have been released from Dolcoath, Grenville, and Tincroft. That they were hard-working citizens and splendid miners there is no question, but that they require sympathy, at least the younger of them, is doubtful. For some of them the cloud has acquired a silver lining, since we learn from a recent dispatch that 200 miners from Cornwall have arrived and gone to work in the silver mines of Cobalt where the shortage of competent men has been felt for many months. They will earn higher wages and probably in a few years will be better off in every way than if they had stayed at home. Cobalt and Canada will benefit by the acquisition of miners who inherited their mining sense through generations, and men who will be a credit to their adopted country. There is room here in the United States for many times what Cornwall can spare.

"PARIS has struck gold", says a sensational dispatch in a recent morning paper. The discovery is said to have been made at Gief, ten miles from the city of pleasure. It is not a placer deposit but a two-foot vein of gold-bearing quartz, which was cut 80 feet below the surface. It is not clear what the diggers were seeking so far underground when they found gold, but it is stated that the news attracted so large a crowd of amateur prospectors that a large force of police had to be sent to the locality. Gold was found recently in South San Francisco, according to the local newspapers, and no more was heard of it. The later story from Paris is probably a canard, like many others of the same kind. Gold is widely distributed in nature and has been found in every kind of rock; France used to have a number of productive gold mines years ago, notably the La Belliere, Chatelet, La Lucette, Salsigne, and Villaniere. In 1909 the La Belliere made a profit of two million francs. In 1910 the output was 8500 tons of ore yielding 38,733 ounces of gold. 'The Mining Magazine' of March 1911 contained

an article by Mr. Thomas T. Read on this enterprise. The mine is near Nantes on the Loire, in La Vendée, a region in which the Romans mined extensively for gold during their occupation of Gaul. Augustus derived a large tribute in precious metals from the Gauls and it is related that in 15 B.C. the Roman procurator Licinius took the man who was president of the republic and the adopted son of Julius Caesar to a large room full of gold and silver that had been extorted from the natives for the support of the government on the Tiber. At Bourg d'Oisans, in the Isère, is an old gold mine that was worked by the Greeks, the Romans, and the Saracens. It is called La Gardette and was operated by the Count of Provence in 1783 and by two Englishmen in 1862. These notes suggest that a gold mine in France is nothing unusual, but a profitable gold mine close to Paris would be a phenomenon indeed, and altogether subversive of accepted ideas.

Speakers and Speeches

Fluency is a danger, loquacity is a bore, garrulity is a pestilence. Anybody familiar with the proceedings of a convention, such as the recent meeting of the American Mining Congress, is likely to ask why the speaking is not under better control. So many sessions are spoiled by the egoism of some individual wholly oblivious of the fact that there are others on the program. The worst type, of course, is the person having an easy flow of speech and a paucity of ideas; the few real thoughts he has can be seen floating about in his mind, like carp in a pond. There is the man who undertakes to discuss a subject needing scientific precision and brings to bear upon it a large command of inaccurate language, by the use of which he involves his hearers in a mental dust-storm. There are those with the gift of speaking far beyond anything worth while that they have to say. There are others who deliver their opinions like Milton's angels, whose didactic speeches were received with respect and concluded with gratification—to all concerned. All this we write not with malice but with a quiet smile. At Denver we were not victimized to any acute degree, but some incidents of that convention provoke the discussion of a subject that is of real importance to gatherings of the same kind. For instance, a session begins a quarter of an hour late, so that, as between 10 o'clock and noon, there remains an hour and three-quarters. Three, or perhaps four, speakers are listed. One of them reads a paper that consumes an hour, leaving only 45 minutes for the others. The first paper may be a good one, so good indeed that the whole session might better have been devoted to the reading and discussion of it, but the knowledge that others are to come makes one impatient, with the consciousness that the speaker is exceeding his limit; indeed, only a trained speaker and one discoursing on an unusually interesting subject can hold an audience for an hour. Usually the effort tires his hearers and spoils them for subsequent papers. Papers that are read, of course, are less easy to follow than speeches, because the latter are couched in shorter, and more natural sen-

tences. Obviously if a session of two hours, or more, is to be devoted to one subject and to be divided among a number of speakers or readers of papers, it would be best to tell each one how much time is allotted to him, thereby compelling each one to omit or curtail parts of his paper beforehand, so that it might comply with this necessarily drastic method for saving time and patience. Much, of course, depends upon the chairman, but most chairmen are either too inexperienced or too amiable to exercise their legitimate authority, especially when it ought to be directed against the more verbose speakers, who, not infrequently, are persons of some consequence, so accustomed to speaking in public that they find it easy to do so and in the exercise of their facility forget to curb it. At the Mining Congress banquet the toastmaster had a traffic signal, showing 'GO' on one side and 'STOP' on the other, and he used it in fun once or twice, ineffectually. An hour-glass signal, adjusted to the exact time given to each speaker, might be placed in front of him in full view of the audience. That might be an effective reminder, but it would be useless as a check unless applied strictly. Another means for abating a public nuisance might be borrowed from the vaudeville theatre. Once in a while it is the custom to have an 'amateur night', when almost anybody having histrionic or dithyrambic ambitions is given a chance to show what he can do. Under such circumstances, naturally, some device for checking the exuberance of virtuosity is imperative; so the manager employs the 'hook'. When the audience becomes tired of any individual performance, there are cries, sometimes concerted, of "Get the hook". Thereupon a wire hook or loop is extended from the wings so as to drop securely around the body of the victim and hale him hence, amid the jeers and laughter of the audience. Joking apart, it is obvious to anyone familiar with conventions and their antics that some method of assisting the chairman in regulating the proceedings would be a boon and a blessing. As to the speechifying at dinners and banquets, that is being disciplined already, in this country, by the prevailing aridity. Prohibition is a veritable Procrustes for abbreviating speeches. In days when stimulating liquors assuaged the pain inflicted by bores it was possible to listen to long speeches with some approach to resignation, if not oblivion, but now that we are denied any solace but soup and soda-water it is absolutely necessary to make speeches that are crisp and short, and not too many even of them. The idea of talking solemnly on a serious subject is entirely foreign to the spirit that brings men together at dinner, yet attempts at elaborate discourses are still made occasionally by pachydermatous persons. A dinner must be eupeptic, and to be that the things that are said should be as easily assimilated as those that are eaten are comfortably digested. In these days the lack of wine makes us sensitive to the gastronomic imperfections of public dinners, therefore all the greater is the need for utterances that do not provoke mental dyspepsia. The standard of the speeches on such occasions is going to be much more exacting, and the

verbal meanderings of self-complacent pseudo-orators are going to be taboo. At least we hope so. If prohibition induces saner ideas on these matters we shall have reason to be grateful to the 18th Amendment; if not, we shall have two reasons for being bad-tempered. In conclusion we quote the suggestion of a distinguished Judge that most people are so fond of talking that they lavish much praise on silence in others, as poverty is lauded as a virtue because every one wants to be rich.

Industrial Relations

We are glad that we published the three articles by Mr. W. R. Ingalls, on the labor question, because, among other reasons, they have elicited discussion by Mr. C. V. Corless, whose thoughtful contribution we publish on another page of this issue. Dr. Corless is well known for his interest in the subject of industrial relations; he has contributed several valuable essays to the transactions of the Canadian Mining Institute; he is an earnest student of the question, as his latest utterance proves. It is well that the other side of the controversy—for unfortunately it is that—should be presented. Mr. Ingalls represents what is called the reactionary view; his sympathies are capitalistic; in economics he is a Tory. On the other hand, Dr. Corless represents the progressive view; his sympathies are with the workers; in economics he is a Liberal, if not a Radical. Men of both types are needed for the purpose of establishing a sane balance of ideas, although, of course, we hope and believe that the liberal view will prevail. This view takes for granted that, as Dr. Corless says, "we are dealing not with materials and machines but with men". To make it more precise we would place an 'only' after "machines". In order to produce the maximum of useful effect it is necessary that the men as well as the machines become the object of economic solicitude, which means that as we recognize the machines to be made of metal, so we shall recognize continually that the men are human beings like ourselves, with feelings, as well as hopes and ambitions, that are at least as delicate as the fine edges or the intricate wheels of the machines they use. Undoubtedly it is desirable to develop a sense of personal achievement among the workers, that is, to stimulate an interest in their task, lifting it thereby from drudgery to accomplishment. We have been reading the book by Mr. Whiting Williams entitled, 'What's on the Worker's Mind'. The author went to work as a laborer in a number of plants successively, including a rolling-mill, a foundry, a railroad shop, a coal mine, an iron mine, and a dockyard. He came into intimate contact with many classes of workmen under conditions that enabled him to find out how they were treated, how they felt, and what they wanted. This book ought to be read by everyone interested in human economics; it gives genuine first-hand information. In many instances he found that no arrangement existed for giving proper instruction to the greenhorn; hence, of course, much discomfort to him, and with it a loss of self-respect, besides the inevitable loss of efficiency. A few words of instruction concerning the work to be done would elimin-

ate the need for the foreman whose only word is an oath. Such instruction would save the money now spent in having a boss on hand every minute to prevent blunders. "Most of the workers", says Mr. Williams, "are surprisingly anxious to feel their job important and respectable". It is rarely that the men understand the meaning of the work they are doing or the specific part it plays in the operations as a whole. One reason why they remain ignorant is because a large proportion of the bosses are aliens unable to speak our language. A knowledge of the Slavic tongue is needed by a young American working in the rolling-mills of Pennsylvania! The force consists of a weird mixture of intensely foreign foreigners, who have learned but little English beyond the coarsest expletives. To many men it is a greater satisfaction to do their work in their own way, for later inspection, than to have a foreign boss cursing them every time they make a false move. Evidently these people ought to be taught our language or we ought to learn theirs, instead of both sides being limited to the use of profanity. The tonnage-men in the coal mines, that is, those working on contract, seem to have the best of it, in that they are on their own initiative and are paid the immediate value of their own efforts. In short, a man must feel the dignity of his job if he is to do well, instead of having an ignorant foreman who assumes that the entire dignity of the job resides in himself. So we come again to the conclusion that much of the inefficiency and unhappiness of manual labor is due to the bad selection of foremen, who, of course, serve as the connecting link between the management and the men. By the treatment a man gets from his immediate boss he judges the 'higher ups'.

Another remark by Dr. Corless appeals to us, namely, the tendency to ascribe too large a part of any great economic success to one person. It is easier to envisage the success of an individual than that of a group of men or an organization; besides it is more romantic to have a hero, on whose head the chaplet of palm-leaves can be placed gracefully. Moreover, the irresponsible journalism of the day likes to dwell upon the sensational aspect of any industrial enterprise, and it becomes more sensational when ascribed to an individual whose portrait can be presented in garish verbal colors than when credited to a combination either of favorable circumstances or of capable co-workers. Such men as Messrs. Rockefeller, Carnegie, and Schwab, the types of successful captains of industry, are poor things if examined closely and critically, but they serve to epitomize the highly organized activities of a cohort of clever and resourceful men, most of whom were willing to accept their leader as the expression of their own aggregate endeavor. In their willingness to subordinate their own prominence or distinction in achieving the purpose of their work they exhibited the highest form of what we call civilization, which is based upon the subordination of self-assertion for the sake of the community. Dr. Corless says a true thing when he asserts that similar co-operation is needed between all those engaged in industry. "The most profound problem in industry arises from the search for a

method of organization that will result in enlisting in its service the highest degree of brain-power, that is, intelligence, good-will, and will-power, of all those engaged in it." Capital includes many things besides money, as for example, the trained technique of an engineer or the trained muscles of a good workman. So long as we recognize the right and the desirability of transmitting property from father to son, or to whomever the possessor of it may see fit, we shall have to realize that the employer brings to industry something more than either his own brains or the muscles of his workmen, or the muscles and brains of both. The accumulated effort of a man or of his predecessors is turned into a reservoir of capital, and unless he can have the last word in the disposal of it, subject to taxation by the State under the protection of which it was accumulated, he will be deterred from extra effort. In short, so long as the reward of industrial initiative is to be recognized in the form of accumulated profit, it will be impracticable to divide the control of enterprise on any basis of equality with the workers who do not contribute to the monetary capital without the aid of which the enterprise could not have come into being. The Soviet system is based on the fallacy that capital can be rendered unfruitful without killing industrial development; on the contrary, it is the reservoir of stored energy from which comes the power to start and to develop the beneficent activities of our industrial civilization.

Another letter on a different phase of the same subject comes to us also from Canada. Mr. F. J. Bourne has the courage of his convictions and gives one the impression of sincerity, without which any discussion of this kind is a mere tinkling of cymbals. His contribution is prompted by the thoughtful letter from Mr. Sam Lewisohn appearing in our issue of November 6, but he takes a less cheerful view, emphasizing the recalcitrancy of organized labor. Much that he says is true, although unpleasant; for instance, that labor-unionism is a trust to raise wages just as combinations of corporations, despite the law, continue to operate as trusts to raise the prices of commodities. The story of sugar, shoes, and paper during the last two or three years is eloquent on that score. Of course, as he says, it is easy when prices are rising to give employees a share of the profit, but when the economic pendulum swings the other way there is no suggestion of decreasing wages with a view to assisting the employer. The sliding scale refuses to operate both ways. The sense of fair play is undeveloped for one thing; another is that wage-earners live in such a hand-to-mouth way that they cannot reciprocate the action of their capitalistic employers. Mr. Bourne asserts that the humane method in dealing with labor has failed; he thinks that industrial relations must be placed on a purely warlike basis; both sides becoming so organized that they can deal with each other collectively. We commend the book by Mr. Williams, in which he will find many proofs of the fact that the human factor continues to operate in many curious ways. In the recognition of it, plus fair play, lies the best hope of solving the complex problem of industrial relations.

DISCUSSION

Labor the Holder of the Nation's Wealth

The Editor:

Sir—In recent issues of your paper you have repeated, from 'The Annalist', a lengthy discussion by W. R. Ingalls which, though it contains few conclusions that are new, indicates that his ripper studies have served to confirm his economic views already expressed through various mediums widely read by mining engineers. His carefully compiled data and the precisely expressed conclusions drawn from them make this essay, as well as the author's former papers on kindred subjects, valuable contributions to current economic and social literature. The accuracy, clearness, and precision of statement of the trained and scholarly editor, shown in his lucid discussion of the difficult and complex subject of the division of the national income, add to the pleasure and profit of the reader.

If, therefore, criticism is offered expressing disapproval of some of the views expressed or implied in his essay, such unfavorable comment does not arise from lack of appreciation of it as a discussion of economic facts and conclusions. It is rather his implied attitude toward the most burning social and economic question of the day, the problem of industrial relations, that appears to me to be regrettable. And this strained situation between labor and capital can never be bettered by adopting the harsh tone of superiority which appears to be displayed in such statements as the following: "If people can get into their heads the idea of the division of goods instead of the division of dollars they may become less extravagant in the use of goods and more fruitful in the production of them. The evils of the time and their corrective are condensed in this formula." Regarding the latter generalization, few will be prepared to accept so sweeping a statement. Some of the evils of the time may be "condensed in this formula", but undoubtedly many are not. It is this tactless air of arrogance and finality which, I fear, may quite unintentionally do harm by intensifying the feeling of antagonism already existing.

Let us grant, for purposes of argument, that his estimate as to the distribution of the national income is substantially correct and that he is correct in ascribing the cause of the worldwide unrest to "the desire of the wage-earner for a larger share of the product of industry"; and let us grant further the inevitable corollary of these two admissions, namely, that this desire can be fulfilled and the unrest lessened only by increasing the divisible national income of economic goods and services, which implies increasing the efficiency of the workers. The

question then instantly resolves itself into one not of facts but of ways and means. In modern large-scale industry these ways and means are largely, if not mainly, questions of organization. We are dealing not with materials and machines but with men. These men have like feelings and intelligence to ourselves; they will contribute their best to industry only when this fact is fully recognized in the method of organization and the spirit underlying it. If the method and spirit of industrial organization is such as fully to recognize their feelings and intelligence, if the organization is so designed as to allow them to share reasonably in such responsibilities and information as intimately concern their own welfare, if it is so thought out as to cause them to be personally interested in what they are doing, to yield them a reasonable sense of personal achievement, and to convince them that they will share fairly in any increase of product resulting from their increased effort, there will be the strongest possible incentive by increase of effort to fulfil their natural desire for a larger share of the product. But intelligent workmen have a right to see for themselves whether the division is just or not. In future they will no more be inclined to accept statements as to the proper and just division of income, whether national or of any given industry, without having such knowledge as will be convincing, than are other classes of men. This does not mean that every workman will understand every detail any more than it implies similar knowledge on the part of every shareholder in a business enterprise. But it does mean that the workmen's representatives, equally with the shareholder's representatives, will be fully informed, will share in the responsibility of shaping the conditions under which the industry is carried on, and will have a say in the division of the product. Statements and arguments regarding the division of either national or corporation income, made with the apparent purpose of those given by Mr. Ingalls, will almost certainly not tend to lessen the existing suspicion. The reason is that workmen's representatives under existing industrial conditions have not such access to the necessary original facts and data as would really convince them. Though I recognize the difficulties to be surmounted, perhaps as fully as any other person in a responsible position in industry, I can see no ultimate way out of the present difficulty other than by fully and frankly sharing the responsibilities and information with labor.

Those who are making a close study of the evolution of modern industry can see the movement in this direction going on under their eyes. Scarcely a month goes by in which we do not learn of one or more firms adopting

the representative principle in whole or in part. It is, of course, generally advisable to adopt it progressively. This gradual increase in responsibility is the only known successful method of educating men to bear their share of it. The carrying of responsibility will prove here, as experience shows it always to have proven in other aspects of life, to have a very sobering effect.

"The economists of the coolly calculating school", who pride themselves on their want of idealism and who view their coolly calculated conclusions in the "cold and sterile" light of pure intellectuality, are not more fully aware of the truth of such axioms as that "people cannot divide among themselves more than they have got" and sundry other gems of wisdom, than are other students of economics, engaged in industry, who recognize also the bearing on the industrial problem of a number of other sciences equally relevant to its solution. The latter group probably differ from the former not so much in belief in, or attempt to reach, the economically impossible (as Mr. Ingalls appears to believe) as in their practical idealism leading to the belief that, if all the elements of the problem, including the psychological and ethical as well as the economic, are properly considered, a way out of the present industrial deadlock can be found. They believe too that the presentation of economic discussions in the manner and with the apparent purpose of his essay is likely rather to increase than to lessen the difficulty of solving the present deadlock; in other words, that such manner and apparent purpose are psychological and tactical blunders, in view of the difficult and delicate situation already existing.

Mr. Ingalls makes large assumptions as to the share of the product of unusually successful industries due to "Capital" and "Mind". The "directing mind" that conceives and initiates a successful enterprise is, aside from heredity, merely the end-product of educational and other social influences and opportunities, tracing their roots to the very beginning of civilization. The good fortune (in the form of environment for which the industrial leader can in no way claim credit) which has made it possible for him to develop his ability effectively, is in itself a social obligation for which his successful personal efforts should be considered in a large part a return. Aside from this personal effectiveness, it is worth while to consider briefly his merit in relation to the enterprise. Let us illustrate this, as does Mr. Ingalls, by reference to the successful exploitation of any one of the large Western 'porphyries'. Here again, necessary types of machinery, methods of concentration, technique of construction, and operation of cheap and large-scale reverberatory smelting and converting plants, were ready to hand, the end-products of the technical contributions of large numbers of mechanical, metallurgical, and other technical ancestors. And even when the conception that mentally pieced all these factors together began to be realized, the actual bringing of them together was due to the loyal co-operation of many who were willing to bring to bear on the problem their ability and training both in brain and brawn. No one knows better than Mr. Ingalls

that not only conception is needed but also daring, and that sometimes the daring wins—and, alas, sometimes it does not. But our tendency to hero-worship causes us generally to ascribe far too large a part of any great success to some one person.

No, mind or brain-power, in relation to any large enterprise, is not concentrated in one, or even in a few, individuals, as Mr. Ingalls would lead us to believe. It is widely distributed. Labor and mind in industry are not separable *in fact*, though they may abstractedly be separated *in thought*. They are united, in variable proportion, in every individual engaged in industry. Probably the most profound problem in industry arises from the search for a method of organization that will result in enlisting in its service the highest degree of brain-power—intelligence, good-will, and will-power—of all those engaged in it. I can find nothing in any of Mr. Ingalls' discussions looking in this direction. He appears to me to have a quite unwarrantable view of the relative importance of the "directing mind" of the industrial leader as compared with that of the many minds who in varying degrees, directly and indirectly, contribute equally essentially to the success of any large enterprise. There is nothing in leadership that should cause arrogance; quite the contrary; leadership is largely the result of accident.

Again, the author appears at times to confuse the ideas 'Capital' and 'Capitalist'. Capital remains, and will always remain, no matter how wide or how equal the distribution. If every worker should tomorrow by his own energy and thrift become an industrial share-owner or capitalist, the world's capital, its means of production, would not be altered by the change in ownership. But it would have a steady effect on industry and society in general, and it would result in greatly increasing production and consumption, that is, the more widely distributed ownership would advance human welfare in so far as this is measurable in material things. It should therefore be one of the aims of industrial leaders, that is, of those who understand the aim of true leadership to increase human betterment, both to increase the quantity and to widen the distribution of wealth, using, of course, only such means as are just to all who are engaged in industry. The chief objection to the accumulation of too great amounts of capital in the hands of individuals is similar to that arising from entrusting to one man too great power of any kind. Even a Marxian socialist or a Russian bolshevist cannot deny the necessity of capital. Its accumulation in too great pools, giving great power and superabundance to a few individuals, is the greatest of the underlying causes of both movements.

Capital is stored labor, whether such labor was the effort of brain or brawn. But it is well not to take too material a view of capital. Much of it is stored in the disciplined mind and trained muscles, as well as in the effective organization, of those engaged in industry. It is unsafe to place too great reliance on such statistical figures as Mr. Ingalls compiles. The most important part of the capital of civilization is intangible. It cannot

be estimated and tabulated. Many of us have worked and saved most of our lives, but have accumulated very little tangible capital. The tangible capital of civilization is easily destroyed and easily replaced, because of the intangible capital, which is latent and potential, and which brings into existence tangible capital as needed or desired. This intangible capital, which is the summation of civilization itself, is of inestimable, but almost infinite, value.

As a contribution to economic discussion, pure and simple, the articles by Mr. Ingalls are well worthy of critical study; but, if viewed from the standpoint of the problem of the misunderstanding of labor and capital, as here and there throughout his essay would appear to be his purpose, his discussion may increase the already existing strain. I am optimistic enough to believe that a way out of the present industrial impasse can be found, in fact, that a start in the right direction has already been made.

The invention of the steam-engine marked the beginning, and the world war will probably come to be looked upon as marking the end, of the period or epoch of more purely mechanical development of industry. During this period the development and practical applications of mathematical, physical, chemical, and other material sciences were in the ascendant. The dazzling successes achieved concentrated almost every energy on the material aspects of wealth production and tended to divert attention from the only end that could make increase in material wealth worth while, the highest average of human welfare.

In the industrial epoch on which we are entering, the development and application of the sciences that deal with human beings and their organization into industrial and other social groups—economics, civics, ethics, sociology, psychology, industrial organization, history, and the like—will receive steadily increasing attention. Thus will the evils of an unbalanced industrial development come to be eliminated, a better balance be struck, and the highest benefits from the further development and application of the material sciences be achieved.

Because of his position in the development of industry, much of this new responsibility will rest on the engineer. But great discretion is needed on the part of those whose profession places them thus in the position of "a buffer between labor and capital". I am entirely in agreement with Mr. Sam Lewisohn that special training and experience are badly needed by engineering students as a preparation for this most important function in industry.

C. V. CORLESS.

Coniston, Ontario, November 11.

The Human Factor in Mine Management

The Editor:

Sir—I have read with much interest the letter by Mr. S. Lewisohn on this subject. He speaks of the difficulty of getting the mine manager to adopt modern methods in handling men. The question is, are modern methods effective? I was connected some years ago with a concern

that started out to run its mine on the principle of the Y. M. C. A. We established a gymnasium, reading-room, held dances, etc., and made an honest effort to promote good feeling between the management and the men. The experiment (like hundreds of others) was a failure. A few of the more intelligent men appreciated our efforts. The majority looked upon it as a sign of weakness, and we finished up with a most disastrous strike, which nearly ruined the company.

There are no doubt cases where companies have been successful in building up an organization that had the interests of the company at heart, but these cases are rare, due largely to a rabid press and the work of radical labor leaders.

Mr. Lewisohn, I think, rather loses sight of the fact that human nature is complex, and very selfish. The director of a company expects a manager to handle his job and produce results, or his place is taken by another man. He has no union to protect him, and he is handicapped by handling men that can demand practically what they like (and get it) if their organization is strong enough. We have an example of this in the action of the railroad men of the United States and Canada. They say to the vast majority of brother-workers in these countries, "We know that although most of our railroads are bankrupt, and have to raise their rates to enable them to pay our present high wages, we are making life much harder for thousands of our fellow-workers, but we have decreed that our wages shall be such, and the public must pay the bill." And then they gather together and solemnly discuss The Brotherhood of Man.

We have another example of this among the coal-miners of Wales. Lloyd George, a Welshman himself, has for the last twenty years, showered benefits of every description on the miners of Wales. Minimum wages, old-age pensions, shorter hours, etc., are all the results of his untiring efforts to introduce the human factor into the mining industry. And the pity of it all is, he is the most hated man in Wales today.

Mr. Lewisohn says the day has passed when employers can ride roughshod over their employees. He is right, although for the last five years the shoe has been on the other foot, and the employees have ridden roughshod over the employer, and have not in many cases considered the human factor, as regards the employer. As regards the unions, I agree with Mr. Lewisohn that a union well run is a benefit to any industry, although I do not believe that trade-unionists will ever solve industrial unrest and discontent, because their principle is wrong. We have in Canada, roughly speaking, 400,000 union workers who dictate to the other seven million inhabitants of Canada the price they shall pay for the essentials of life. No one with any sense denies the right of any man by organizing to force the public to pay him the highest he can get for his commodity, which is labor, when the Government allows large corporations to form trusts and force the people to pay the highest prices for the common necessities of life. Labor-unions also are trusts formed with a view to making all they can out of their fellow-men.

In my opinion if trade-unionism is going to be a success, it must come down to a common-sense basis, and teach its members to share the responsibilities of the management. Collective bargaining in the past has been a joke. As from a labor standpoint it only means, "I want a standard wage whether your business is paying or not." If, on the other hand, the labor leaders would set a wage based on the profits earned by a company, and accept a reduction when there was no profit, I can see a solution of the question.

We are, Sir, living in a sentimental age. You can hardly pick up a paper but what you read of the woes and sorrows of the man that works. As a matter of fact, there are no countries in the world in which workers are better off and more discontented than in Great Britain, the United States, and Canada. The manufacturers and employers of labor in Great Britain have worked the 'human factor' to such a pitch that before the War it was notorious that the output of a British workman was only one-half that of the mechanic in the United States or Canada.

As regards the failure to find mine managers that consider the human factor, I think Mr. Lewisohn is mistaken. I have been associated for many years with mine managers, and my experiences have been the reverse. Far too many are prone to take the easy road and go with the tide, and settle everything in favor of peace. This attitude is largely responsible for the present conditions of the mining industry. Prospecting is almost at a standstill. Many small companies (with, in some cases, poor stockholders) cannot afford to operate because costs are too high. This imposes a great hardship on the miner, as we have winter upon us and many will be out of work, and for this they cannot blame the small operator who is trying to develop his property. The miner usually calls your attention to the few large mines that are paying dividends. He seldom thinks, or will he discuss the hundreds of thousands of dollars that has been spent on unproductive prospects.

In handling men we must never lose sight of the fact that there must be mutual respect, which can never be bought through gifts.

We all know that Australia has gone through a system of modern innovations that was the admiration of the labor world. It has proved a failure. When any government takes a man by the hand and legislates his life for him, you kill ambition and thrift. Why should a man provide for the future when his life is cut and dried for him?

In talking about modern ideas, it is well to remember that although the world has seen some great advances in the arts and sciences, human nature has changed but little. We still have our ambitions, we love, and we hate, and in fact act very much as did our ancestors hundreds of years ago. Over all is thrown a thin veil of civilization. Before 1914 many of the leading statesmen of the Anglo-Saxon world said war was a thing of the past, but this theory did not materialize. The War came, with all its attendant horrors, and the thinking men of the world are forced to admit that human passions are much the same

today as yesterday. I am convinced that what we need in the world today is more plain speaking, an honest press, and last of all, less greed and more courage on the part of directors of companies. Many a manager has put up a good fight against most unjust claims, and lost out, because his directors would not back him up. I am sure if every manager would pay the men he has in his employ the best wages he can, and if the company is prosperous, give a bonus in addition, it would stimulate ambition, and do more good than all the theories. The men are not children, and the great majority of them distrust the good intentions of the manager unless they are accompanied by a rise in wages.

I fear I have wandered away from my subject, but I am sure Mr. Lewisohn will admit that the managers of most of the large railroads and many of the industries of North America have not failed in their duty to their employees. They have recognized the human factor to a great extent, and the very industries (notably the railroad workers) in which they are engaged have the most discontented employees. Trade-unionists have not solved the problem of social unrest, and they never can until they educate their members up to a higher standard than (like *Oliver Twist*) to be eternally wanting more.

The fact is, employers of labor in America have been asleep at the switch. The labor-unions by good organization (and practical control of the press) are more or less masters of the situation, and the employers have done little or nothing to put their case before the public.

My conclusions are as follows: The human factor in dealing with labor has been tried and found wanting. The same can be said of the labor-unions. The solution is for all the employers to organize and meet organized labor on its own ground. It is only by doing this that we can hope to succeed.

The human factor must remain in business, but it must not be one-sided, or collective bargaining will count for naught.

F. J. BOURNE.

Cobalt, Ontario, November 17.

RADIUM is the most valuable element in the world; one gramme of radium, which is about a thimbleful, costs \$120,000, as opposed to \$150 for an ounce of platinum. So powerful is it when mixed with other materials that even a minute particle is effective in making surfaces self-luminous for years. It is this quality which makes radium-luminous material commercially possible. The great value of radium is due to its scarcity, and to the great difficulty in isolating it after it has been found. Much of the radium of the world now comes from the carnotite ores of the United States. A great portion of this comes from the Undark radium mines in the Paradox valley of Colorado. The ore is found in narrow seams. It is sorted and packed in 100-lb. sacks and transported 60 miles to the nearest railroad station on the backs of burros and mules. Thence it is shipped in earload lots across the continent to an extraction plant in Orange, New Jersey. 250 tons of ore yields one gramme of radium.

Minerals Separation's Position Under the Patent Laws and the Anti-Trust Laws

By Gilbert H. Montague

*Minerals Separation owns, controls, and is interested in 23 United States patents. Of these, three only have been litigated: No. 835,120 (fraction of 1% oil), No. 962,678 (soluble frothing-agents), and No. 1,099,699 (phenol or cresol, cold, without acid). None of the remaining process patents, most of which cover merely some variant or alleged improvement of one of the above processes, and none of the apparatus patents, all of which together admittedly cover only a few of the many types of machines capable of use in flotation, have ever been litigated or invoked by Minerals Separation in any court against any alleged infringer.

Taking up these three patents, which alone have been litigated by Minerals Separation:

No. 835,120 (fraction of 1% oil) was patented in the United States on November 6, 1906, by three British subjects, Messrs. Sulman, Picard, and Ballot. Now 962,678 (soluble frothing-agents) was patented in the United States on June 26, 1910, by the same Mr. Sulman and two other British subjects, Messrs. Greenway and Higgins. No. 1,099,699 (phenol or cresol, cold, without acid) was patented in the United States on June 9, 1914, by the same Mr. Greenway. Considerable mystery has been thrown by Minerals Separation around the present ownership of these patents, but so far as can be ascertained (see testimony in Federal Trade Commission v. Minerals Separation, Ltd., et al., pp. 40-41, 324-325, 1015-1016) such ownership is somehow suspended between the parent company, Minerals Separation, Ltd., a British corporation, and its subsidiary, Minerals Separation North American Corporation, which the British parent company caused to be organized under the Maryland law in the midst of the Great War.

"TO PROMOTE THE PROGRESS OF SCIENCE"

The Constitution of the United States (Art. I, Sec. 8, Clause 8) provides that Congress shall have power "to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries". That Congress was empowered simply "to promote the progress of science and useful arts", and was authorized to secure "for limited times" to "inventors the exclusive right" to their "discoveries" only in so far as this would "promote the progress of science and useful arts" and that the patent-owner's rights under

the Constitution are thus conditioned by the Constitutional purpose "to promote the progress of science and useful arts" must always be remembered, and if my reference to this almost forgotten Constitutional provision, and to some often overlooked duties and obligations of patentees arising thereunder, seems sometimes too frequent, it is only because the arrogance of patentees in general, and Minerals Separation in particular, makes it constantly necessary to recall that, by the very words of the Constitution, Congress had no power to secure "for limited times" to "inventors the exclusive right" to their "discoveries" excepting in so far as such "securing" should "promote the progress of science and useful arts".

With this single Constitutional purpose in view, Congress has enacted that after filing in the Patent-Office a "written description" of his "invention or discovery", and "of the manner and process of making, constructing, compounding, and using it, in such full, clear, concise, and exact terms as to enable any person skilled in the art or science to which it appertains, or with which it is most nearly connected, to make, construct, compound, and use the same", and "particularly point out and distinctly claim the part, improvement, or combination which he claims as his invention or discovery" (U. S. Revised Statutes, Sec. 4888, as amended, Act March 3, 1915, c. 94, Sec. 1), and after establishing, to the satisfaction of the Patent-Office, the fact of his "invention or discovery", the inventor shall then receive "a grant to the patentee, his heirs or assigns, for the term of seventeen years, of the exclusive right to make, use, and vend the invention or discovery throughout the United States, and the Territories thereof, referring to the specifications for the particulars thereof" (U. S. Revised Statutes, Sec. 4884). This grant, be it always remembered, is conditioned by the Constitutional purpose "to promote the progress of science and useful arts". Many times the courts have held that only in so far as the patentee has fulfilled this Constitutional purpose, and through his specifications and claims on file in the Patent-Office disclosed his "invention or discovery in such full, clear, concise, and exact terms as to enable any person skilled in the art . . . to make, construct, compound, and use the same" is the patentee entitled to a patent, and that for conduct tending to frustrate this Constitutional purpose, such as fraud, or intent to deceive, or excessive claims, the patentee must forfeit his patent.

LITIGATED PATENTS SOON EXPIRE

Returning to the three patents that alone have been litigated by Minerals Separation:

*The author is of counsel for the American Mining Congress in the proceedings against the Minerals Separation company before the Federal Trade Commission. This paper was read at the meeting of the American Mining Congress at Denver on November 17, 1920.

No. 835,120 by assignment grants to the British parent company and to its controlled American subsidiary, Minerals Separation North American Corporation (or to the latter alone, according as may appear when the mystery of ownership is cleared up), "for the term of seventeen years", that is, until November 6, 1923, "the exclusive right to make, use, and vend . . . throughout the United States, and the Territories thereof" such "invention or discovery" as the patentees "particularly point out and distinctly claim" in respect of their so-called "fraction of 1%" oil process. Similarly, No. 962,678 grants to the same companies, until June 26, 1927, similar rights in respect of the so-called "soluble frothing-agents" process, and No. 1,099,699 grants to the same companies, until June 9, 1931, similar rights in respect of the so-called "phenol or cresol, cold, without acid" process. By their own terms, therefore, and by the express language of the statute, these companies must cease exercising these rights on November 6, 1923, June 26, 1927, and June 9, 1931, respectively; and by the precise words of the Constitution these rights are conditioned by the Constitutional purpose "to promote the progress of science and useful arts".

What are these rights, which, by the Constitution, the statute, and the patents themselves, must expire anyway in a few years, and by the language of the Constitution are conditioned "to promote the progress of science and useful arts", which now are so aggressively asserted against the entire mining industry by Minerals Separation?

PRECISE LIMITS OF PATENT NO. 835,120

No. 835,120 has been litigated in the so-called Hyde case (Minerals Separation, Ltd., v. Hyde, 207 Fed. 956, D. C. Montana, July 28, 1913; Hyde v. Minerals Separation, Ltd., 214 Fed. 100, C. C. A. Ninth C., May 4, 1914; Minerals Separation, Ltd., v. Hyde, 242 U. S. 261, U. S. Supreme Court, December 11, 1916) and in the so-called Miami case, (Minerals Separation, Ltd., v. Miami Copper Co., 237 Fed. 609, D. C. Delaware, September 29, 1916; Miami Copper Co. v. Minerals Separation, 244 Fed. 752, C. C. A. Third C., May 24, 1917) and in the so-called Butte & Superior case (Minerals Separation, Ltd., v. Butte & Superior Mining Co., 245 Fed. 577, D. C. Montana, August 25, 1917; Butte & Superior Mining Co. v. Minerals Separation, 250 Fed. 241, C. C. A. Ninth C., May 13, 1918; Minerals Separation, Ltd., v. Butte & Superior Mining Co., 250 U. S. 336, U. S. Supreme Court, June 2, 1919).

In the Hyde case, after varying fortunes in the U. S. District Court for Montana and in the U. S. Circuit Court of Appeals for the Ninth Circuit, No. 835,120 (fraction of 1% oil) was sustained by the United States Supreme Court as regards the claims specifying "*the use of an amount of oil which is 'critical', and minute as compared with the amount used in prior processes 'amounting to a fraction of one per cent. on the ore', and in so impregnating with air the mass of ore and water used, by agitation—'by beating the air into the mass'—as to cause to rise it the surface of the mass, or*

pulp, a froth, peculiarly coherent and persistent in character, which is composed of air bubbles with only a trace of oil in them, which carry in mechanical suspension a very high percentage of the metal and metalliferous particles of ore which were contained in the mass of crushed ore subjected to treatment" (Minerals Separation, Ltd., v. Hyde, 242 U. S., 261, 265), and was rejected as indefinite as regards the claims specifying a "small quantity of oil" (p. 271).

In the Miami case, the Circuit Court of Appeals for the Third Circuit started from the point settled by the Supreme Court decision in the Hyde case, that is, "that invention resides not alone in critical proportion of oil but also in air and agitation" (Miami Copper Co. v. United States, 244 Fed. 752, 758). "It is to be noted," said the Circuit Court of Appeals, by Judge Woolley writing for the Court, "that the Supreme Court did not construe the patent or determine its scope, for it had no occasion to do so" (p. 758). Accordingly, the Circuit Court of Appeals proceeded "to construe the patent in the light of that finding and determine whether the defendant's practices of aeration and agitation in connection with its admitted use of the critical proportion of oil, are within or beyond the scope of the patent" (p. 758). The Circuit Court of Appeals then considered the contention of Minerals Separation, Ltd., that "whenever the modifying agent of the patent [oil] is used, a person infringes who gets air into the pulp in any fashion and agitates the mixture by any means to a sufficient extent to cause the mineral particles to attach themselves to air bubbles and to rise therewith above the top of the mixture in a collection of bubbles and metal particles, to wit, froth" (p. 758). This obviously was an attempt by Minerals Separation to shift from the narrow ground that it previously had assumed, and that the Supreme Court in the Hyde case had adopted, and to place the patent upon another, and quite different, ground, which would be free from the inconvenient limitations implied in the position that Minerals Separation had assumed, and that the Supreme Court had sustained, in the Hyde case. The Circuit Court of Appeals rejected this contention and said: "The contention of the plaintiff at least omits the very definite limitation of the patent to the results obtained by the use of oil within the described proportions, and also the equally definite disclosure of an agitation in violence and duration greater than before employed" (p. 758). Construing No. 835,120, the Circuit Court of Appeals declared that the patentees "first told the art that a maximum metal recovery could be had from a minimum oil content", which "disclosure alone, interesting as it was, would have been valueless to the art and would not have entitled the discoverers to a patent until they told how and by what medium that phenomenon could be brought into practical use" and that accordingly the patentees "proceeded by further disclosures to tell the art that the way to produce the desired fomentation is by . . . agitation 'greater than any different from that which had been resorted to before' . . . Agitation was thus made the practical element o

their patented process, and by their patent disclosures they told the art that agitation was the secret by which the principle of their discovery could be unlocked and used" (p. 765). The Circuit Court of Appeals held that the first, second, and third flotation processes installed by the Miami company included agitation equivalent to that described in No. 835,120 and therefore infringed the patent, but refused to pass upon the so-called "fourth process" then being used by the Miami company. Discussing the Miami company's second process, the Circuit Court of Appeals said: "If the only agitation to which the pulp was subjected . . . was the agitation of the Callow cells, we would not say that that agitation . . . constituted infringement" (p. 768). One of the judges, it should be noted, dissented, and held that neither the second nor the third process of the Miami company included the agitation of the patent (pp. 775-792). That the Circuit Court of Appeals has no intention of hastily declaring the so-called "fourth process" used by the Miami company, or the different variants of this process, used since 1917, to be infringements of No. 835,120 appears from the Court's refusal, in June 1920, to hold at this time that the Miami company is violating the Court's decree in using any of these variants or substitutes.

In the Butte & Superior case, after varying rulings by the U. S. District Court for Montana and the U. S. Circuit Court of Appeals for the Ninth Circuit, the U. S. Supreme Court on June 2, 1919, held that the "essence of the discovery" covered by No. 835,120 was the *reduction* of the total amount of "oily substance" used in the process to any "fraction of one per cent on the ore", plus "*vigorous agitation*", resulting in "flotation mainly from the inclusion of air bubbles introduced into the mass by agitation. (Minerals Separation v. Butte & Superior Mining Co., 250 U. S. 336, 346-347, see also 341-2, 344-7).

Minerals Separation, Ltd., the British parent company, and its controlled American subsidiary, Minerals Separation North American Corporation, began suit upon No. 835,120 against the Nevada Consolidated Copper Co. in September 1919, and against the Magma Copper Co. in January 1920, both in the U. S. District Court for Maine. Both mining companies have filed elaborate answers, which foreshadow their defence that the processes they are using are wholly different processes, lying outside No. 835,120, because they depend upon air bubbles introduced or generated not by "agitation" but solely by Callow or pneumatic cells, and do not depend upon, nor in any way involve, the "vigorous agitation" which the Supreme Court in the Hyde case and in the Butte & Superior case, and the Circuit Court of Appeals or the Third Circuit in the Miami case, held to be essentially characteristic of No. 835,120 (fraction of 1% oil).

PRECISE LIMITS OF PATENT No. 962,678

No. 962,678 (soluble frothing-agents) has been litigated only in the so-called Miami case (Minerals Separation v. Miami Copper Co., 237 Fed. 609, D. C. Delaware, September 29, 1916; Miami Copper Co. v. United States,

244 Fed. 752, C. C. A. Third C., May 24, 1917), where the Circuit Court of Appeals for the Third Circuit sustained the patent, as to four of its claims, in which the frothing-agent is "*a small percentage*" of one or more specified soluble "organic substances" (instead of oil as in No. 835,120) and the "mixture is thoroughly agitated" or "vigorously agitated" by "beating air into it" (Miami Copper Co. v. Minerals Separation, 244 Fed. 752, 771-774). "Here [in No. 962,678] as well as there [No. 835,120]", said the Circuit Court of Appeals, by Judge Woolley writing for the Court, "the decision turns upon the kind and degree of *agitation* employed by the defendants . . . what has been said about infringing agitation in the oil process [No. 835,120] must also apply to the same agitation when considered in reference to the second process [No. 962,678]" (p. 774).

Minerals Separation and its American subsidiary began suit upon No. 962,678 (soluble frothing-agents) against the Nevada Consolidated Copper Co. in February 1920, and against the Magma Copper Co. in January 1920, both in the U. S. District Court for Maine. Both mining companies have filed elaborate answers, which foreshadow their defence that the processes which they are using are wholly different processes which lie outside No. 962,678 because they depend upon air bubbles introduced or generated not by "agitation" but solely by Callow or pneumatic cells, and do not depend upon, or in any way involve the "vigorous agitation" which the Circuit Court of Appeals for the Third Circuit in the Miami case held to be essentially characteristic of No. 962,678.

PRECISE LIMITS OF PATENT No. 1,099,699

No. 1,099,699 (phenol or cresol, cold, without acid) has been litigated only in the so-called Miami case (Minerals Separation, Ltd., v. Miami Copper Co., 237 Fed. 609, D. C. Delaware, September 29, 1916; Miami Copper Co. v. Minerals Separation, Ltd., 244 Fed. 752, C. C. A. Third C., May 24, 1917), where the District Court held the patent invalid, but the Circuit Court of Appeals for the Third Circuit sustained it. The process covered by this patent consists "in mixing a powdered ore . . . with neutral water containing in solution *a minute quantity*" of hydroxy compounds and "*agitating* the mixture in the cold to form a froth and separating the froth" (Miami Copper Co. v. Minerals Separation, 244 Fed. 752, 774). The Circuit Court of Appeals held that by dispensing with heat and acid by using "*a minute quantity*" of hydroxy compounds (that is, phenol, cresol, etc.) the patentee disclosed an original and novel plant which has broadened and made more simple the *agitation* process of air flotation" (p. 775). Neither Minerals Separation, Ltd., the British parent company, nor any of its subsidiaries, has ever sued anyone else upon this patent.

OCCUPIED ZONE OF MINERALS SEPARATION

Summarizing the rights that Minerals Separation, Ltd., the British parent company, and its controlled American subsidiary, Minerals Separation North Ameri-

can Corporation, have under the only patents that it has litigated.

Under No. 835,120, conditioned always upon the Constitutional purpose "to promote the progress of science and useful arts," the patentees have the "exclusive right", expiring in any event on November 6, 1923, merely to the process of *reducing* the total amount of "oily substances" to any "fraction of one per cent on the ore" and adding "*vigorous agitation*", "greater than and different from that which had been resorted to before"—"by beating the air into the mass"—so as to produce "flotation mainly from the inclusion of air bubbles introduced into the mass by agitation", which right the Court has expressly held does not cover *any process in which the total amount of "oily substances" exceeds "one per cent on the ore", nor any process in which air gets "into the pulp in any fashion", or "by any means" (such as "the agitation of the Callow cells"), different from the "vigorous agitation" mentioned in the patent.*

Under No. 962,678, conditioned always upon the Constitutional purpose "to promote the progress of science and useful arts", the patentees have the "exclusive right", expiring in any event on June 26, 1927, merely to the process of *using* "a small percentage" of one or more specified soluble "organic substances" and *agitating* the mixture "thoroughly", or "vigorously", "beating the air into it", which right, by well-settled law, *does not cover any process in which the total amount of such "organic substances" exceeds the "small percentage" referred to in No. 962,678 (soluble frothing-agents), nor any process in which air gets "into the pulp in any fashion", or "by any means", different from agitating it "thoroughly", or "vigorously", or "beating the air into it".*

Under No. 1,099,699, conditioned always upon the Constitutional purpose "to promote the progress of science and useful arts", the patentees have the "exclusive right", expiring in any event on June 9, 1931, merely to the process of *using* "a minute quantity of hydroxy compounds" without acid and "*agitating* the mixture in the cold to form a froth", which right, by well-settled law, *does not cover any process in which the total amount of hydroxy compound exceeds the "small percentage" referred to in No. 1,099,699 (phenol or cresol, cold, without acid), nor any process in which air gets "into the pulp in any fashion", or "by any means", different from the agitation described in the patent.*

These precise limits of Minerals Separation's three litigated patents define the entire zone which, so far as the courts have decided, Minerals Separation today has any legal right to occupy in the field of flotation.

OCCUPIED ZONE SOON TO BE VACATED

By the express conditions of this occupation, prescribed by the Constitution, the statute, and the patents themselves, Minerals Separation on November 6, 1923, must evacuate the first sector of this occupied zone, which it now holds under No. 835,120; and on June 26,

1927, must evacuate the second sector, which it now holds under No. 962,678; and on June 9, 1931, must evacuate the third and last sector which it now holds under No. 1,099,699.

The plain emphatic intention of the Constitution, the statute, and the patents themselves is that on November 9, 1931, Minerals Separation's evacuation from this occupied zone shall be complete, and that Minerals Separation's present servitude over this occupied zone shall then cease, and that this entire occupied zone shall then be wholly free to everyone.

The "exclusive right" for which the patentees bargained when they "disclosed" their processes and obtained their patents was, as they then well knew, by the Constitution, the statute, and the patents themselves, absolutely and strictly limited to this. After the 17-year period for each patent has expired, freedom to everyone to use these processes, without paying royalty or incurring any obligation of any kind to Minerals Separation was, as the patentees then well knew, one of the absolute essentials of this bargain, because if this essential should fail, then the sole Constitutional justification for this "exclusive right", namely "to promote the progress of science and useful arts", would also fail, and the entire Constitutional purpose would be utterly frustrated. I say, advisedly, "one of the absolute essentials of this bargain" because there is another essential equally necessary to the Constitutional purpose "to promote the progress of science and useful arts". Inventors, engineers, manufacturers, and others, independent of, and competitive with, the patentees, must be permitted and encouraged, at every moment throughout these 17-year patent-periods, to utilize every suggestion which the patentees themselves afford to make every independent and competing "invention or discovery" possible in the area outside the occupied zone of the patents. Suppression, intimidation, molestation, or harassment by the patentees of such investigations of such independent and competing inventors, engineers, manufacturers, and others thwarts the Constitutional purpose "to promote the progress of science and the useful arts", and destroys the sole Constitutional justification for the patentees' "exclusive right". To abstain from these practices is just as much the patentees' duty, under the Constitution and the patents themselves, as is their duty to cease to exercise their "exclusive right" at the expiration of the 17-year patent-periods.

How defiantly Minerals Separation, throughout its career in the United States, has evaded these two duties, appears in the standard license agreements that Minerals Separation has executed with dozens of American mine-operators who have never contested Minerals Separation's patents, who at great cost to themselves have quarterly paid to Minerals Separation the exorbitant royalties exacted under these agreements, and who are now discovering from the Federal Trade Commission's evidence that the royalties which Minerals Separation is exacting from them in some cases several times exceed the royalties paid by their more favored rivals and com-

petitors, and that having executed these agreements they must continue forever to pay these royalties, always handicapped by the lower royalties enjoyed by their more favored rivals and competitors, and after November 6, 1923, June 26, 1927, and June 9, 1931, still further handicapped by competition from rivals and competitors, who, not having executed any agreements with Minerals Separation, will after these dates be free to use the respective processes covered by Minerals Separation's three litigated patents without paying any royalty or incurring any obligation of any kind to Minerals Separation.

STRETCHING SEVENTEEN YEARS INTO ETERNITY

Minerals Separation's first duty, under the Constitution, the statute, and its patents themselves, is to evacuate, sector by sector, on November 6, 1923, June 26, 1927, and June 9, 1931, the occupied zone of Minerals Separation's three litigated patents.

To evade this duty, Minerals Separation annexes to its standard license agreement a "schedule" setting forth these three litigated patents, and also all its other United States patents, 65 in number, none of which have been litigated, and most of which cover merely some variant or alleged improvement of processes or apparatus described in earlier patents, and all of which Minerals Separation has succeeded in obtaining from the Patent Office at the rate of from one to ten new patents each year. The American mine-operator, as a rule, desires to use only one, or at most two or three, of the processes and apparatus described in these 68 Minerals Separation patents. Minerals Separation invariably refuses, however, to give him this permission unless he executes a license agreement, in the standard form of which Minerals Separation recites that "the licensors [Minerals Separation] hereby grant unto the licensees [the American mine-operator] full license power and authority to make, use and exercise any or all of the inventions described and claimed in the letters patent within this license" at such mine as the license agreement specifies, "during the terms of the letters patent within this license or any of them and any extension thereof". Elsewhere in the license agreement, Minerals Separation recites that the "letters patent within this license" mean "all or any of the inventions, processes or apparatus described and claimed in the said letters patent and any letters patent for the concentration of ores that are or may become the property of the licensors [Minerals Separation]". This effectively brings within the phrase "letters patent within this license" all patents which Minerals Separation may thereafter succeed in getting patented, which, judging from past experience, will aggregate from one to ten new patents each year until the end of time. The life of the license agreement, therefore, which runs until seventeen years after the date of the latest patent among the "letters patent within this license" will be, until the end of time, extended each year by the addition of new patents, and the license agreement will thus become perpetual, unless Minerals Separation's plans are upset by the Federal Trade Commission.

ROYALTIES, DISCRIMINATORY AND ETERNAL

Several Minerals Separation licensees, as I have stated, pay royalties which are only a fraction of those charged by Minerals Separation to other licensees similarly situated, whom Minerals Separation has required to execute standard license agreements. Such discrimination handicaps each such standard licensee in competing with his more favored rivals, and its correction is one of the objectives of the Federal Trade Commission's proceeding against Minerals Separation.

The eternal duration of Minerals Separation's licensee agreements presents a situation which insistently calls for relief from the Federal Trade Commission. How it operates upon Minerals Separation's licensees may be illustrated by their plight upon the expiration of the patents covering the only Minerals Separation processes which they may happen to be using.

Assume that a Minerals Separation licensee is using only No. 835,120. On November 6, 1923, this patent expires. The plain emphatic intention of the Constitution, the statute, and the patent itself is that on that date Minerals Separation shall completely forfeit its present "exclusive right" to the process covered by this patent, that Minerals Separation's present servitude on the art through its ownership of this patent shall then cease, and that this process shall then be wholly free to everyone. Mindful of this, the licensee, let us assume, who several years before, in order to obtain permission to use merely this "fraction of 1%" oil process, executed with Minerals Separation a standard license agreement, and who has never contested with Minerals Separation this or any other patent, and who at great cost to himself, has paid quarterly to Minerals Separation the exorbitant royalty exacted by this license agreement, and who has never used any process or apparatus belonging to Minerals Separation excepting only the process covered by this patent now expired, takes out this license agreement and reads it over in the expectation of finding that all his obligations to Minerals Separation have now been fully discharged, and that now he may freely use this process without paying any royalty or incurring any obligations to Minerals Separation or anyone else. His license agreement, and thus his obligation to pay royalties, he now discovers, do not end when the patent expires, but continue as long as he uses the process, continue even while his rivals who executed no agreements with Minerals Separation are absolutely free to use the process without paying any royalty to Minerals Separation, continue even while his competitors who defied Minerals Separation and contested its patent are using the process without incurring any obligation of any kind to Minerals Separation or anyone else, and will so continue until the end of time, with the requirement that he account quarterly and settle promptly with Minerals Separation in the same exorbitant figures, so long as he continues to use the process of this now expired patent.

OTHER CONDITIONS OF SERVITUDE

Article 3 of Minerals Separation's standard license

agreements provides that throughout the eternal life of these agreements, all licensees must disclose and turn over to Minerals Separation the ownership of "every invention or discovery made or used by them which may be an improvement, modification, or addition to any of the inventions specified in the letters patent within this license or may be useful in carrying out any of the processes" above-mentioned, and that all licensees must, so far as practicable, "bind their employees" to turn over to Minerals Separation all such inventions made by such employees, and that no licensee may use "any improvement, modification, or addition to any of the inventions specified in the letters patent within this license" except upon request to, and consent by, Minerals Separation. Articles 6 and 9 provide that throughout the eternal life of these license agreements the licensee "shall not in any way directly or indirectly support or assist third or hostile parties" such, for instance, as the Federal Trade Commission, "in any litigation against licensors", and "shall not without the written consent of the licensors communicate any detail connected with the working of any of said inventions, modifications, additions, or improvements to any third party".

If, as Minerals Separation claims (erroneously, as I believe), these license agreements ought to be executed by every mine-operator practising the art of flotation, it would follow that every mine-operator who by any possibility could interest himself in inventing any improvement in the art, now or at any time in the future, would be perpetually subject to the bondage of Minerals Separation.

Nothing approaching the duration, extent, and burdensomeness of the servitude imposed by Minerals Separation has ever been presented in any reported decision in the State or Federal courts. This intolerable and perpetual servitude Minerals Separation seeks to impose upon the entire mining industry of the United States, and upon all present and future inventive genius which in this or any future generation can by any possibility advance the art of flotation. Compared with Minerals Separation, every other trust that the Government has dissolved under the anti-trust laws pales into insignificance, for Minerals Separation seeks to bring within its combination and monopoly not only all processes and apparatus that its own employees may develop, but also all processes and apparatus that any mine-operator anywhere, who now or at any future time uses flotation, may now or at any future time by any possibility invent or discover. To curb this extravagance of monopoly, and to place limits upon these eternal license agreements, are among the objectives of the Federal Trade Commission's proceeding against Minerals Separation.

OBSTRUCTING THE PROGRESS OF SCIENCE

Minerals Separation's second duty, under the Constitution, the statute, and its patents themselves by which Minerals Separation's "exclusive right" under these patents is conditioned, is not to thwart the Constitutional purpose "to promote the progress of science and useful

arts". This Constitutional purpose requires that independent and competing inventors, engineers, manufacturers, and others should be permitted and encouraged to utilize every suggestion that Minerals Separation's patents afford to develop and exploit every independent and competing "invention or discovery" possible in the area outside the occupied zone of Minerals Separation's patents, and that Minerals Separation should abstain from suppressing, intimidating, molesting, or harassing independent and competing inventors, engineers, manufacturers, and others engaged in such development and exploitation.

In defiance of this duty, the Federal Trade Commission charges, Minerals Separation has tried to prevent independent and competing inventors, engineers, manufacturers, and others from exploiting independent and competing processes and apparatus, has tried to prevent American mine-operators from using such independent and competing processes and apparatus, has falsely and maliciously disparaged such independent and competing processes and apparatus, has falsely and maliciously claimed patent-rights in excess of those actually possessed by Minerals Separation, has maliciously threatened to prosecute American mine-operators who were using such independent and competing processes and apparatus, has seduced, corrupted, and bribed employees of American mine-operators to give Minerals Separation confidential information regarding their employers' operations, and in various ways has tended to suppress, intimidate, molest, and harass the development and exploitation of independent and competing "inventions or discoveries" in the area outside the occupied zone of Minerals Separation's patents, and has thus tended to frustrate the Constitutional purpose "to promote the progress of science and useful arts" by which Minerals Separation's "exclusive right" under its patents is wholly conditioned. These practices attributed to Minerals Separation, which properly belong under another topic announced for this Convention, the Federal Trade Commission proposes to stop.

All these practices, according to the Commission's complaint, Minerals Separation has been committing for many years, with such success that by means of them Minerals Separation has stifled and suppressed the development and exploitation of independent and competing processes and apparatus, and has prevented actual and potential competition from independent and competing inventors, engineers, manufacturers, and others, and has thus obtained that position of power and dominance which now enables Minerals Separation to charge exorbitant and discriminatory royalties

WHAT THE COMMISSION CAN ACCOMPLISH

The Commission's purpose is not to dislodge Minerals Separation from the occupied zone which Minerals Separation succeeded in capturing in its first legal onset upon the American mining industry. That task is being attempted only by the American mine-operators who are now defending themselves against Minerals Separation

suits above described. The Commission's object is to ensure that Minerals Separation shall fulfill its plain emphatic duty under the Constitution, the statute, and its patents themselves, to evacuate, sector by sector, on November 6, 1923, June 26, 1927, and June 9, 1931, the occupied zone of Minerals Separation's three litigated patents, and meanwhile not to suppress, intimidate, molest, or harass independent and competing inventors, engineers, manufacturers, and others now working outside this occupied zone, and that Minerals Separation shall not utilize its ingenious entrenchments, its skilfully planned attacks, its enormous exactions of tribute from the occupied zone under its servitude, its awe-inspiring preparations for extorting colossal indemnities from the outside realm of flotation, and its campaign of commercial *schrecklichkeit* generally, for the purpose of evading this plain emphatic duty.

The Federal Trade Commission, in most of the proceedings which it has heretofore brought, has found, like the Supreme Court in the Standard Oil case (Standard Oil Co. v. United States 221, U. S. 1, 77) "that ordinarily where it was found that acts had been done in violation of the statute adequate measure of relief would result from restraining the doing of such acts in the future". But in the present proceeding, the Federal Trade Commission will find as the Supreme Court of the United States found in the Standard Oil case, that "in a case like this, where the condition which has been brought about in violation of the statute, in and of itself, is not only a continued attempt to monopolize, but also a monopolization, the duty to enforce the statute requires the application of broader and more controlling remedies" (p. 77).

The Federal Trade Commission's authority for devising and applying these remedies is ample under the Federal Trade Commission Act and the Clayton Anti-Trust Act. Adequate remedy in the present situation will never be obtained until the Commission, by explicit directions in respect of the amount of royalties to be charged by Minerals Separation ensures that such royalties are not in excess of what they would have been had not actual and potential competition from rival processes and rival apparatus, and from rival inventors, engineers, manufacturers, and others, been stifled and suppressed by Minerals Separation over a period of years. Merely to enjoin at this late day, the continued practice by Minerals Separation of the particular methods of unfair competition set forth in the Commission's complaint will not immediately revive the actual and potential competition which Minerals Separation has for years been stifling and suppressing. Not for several years, perhaps not for many years, can this competition be revived, nor the mining industry be made safe for rival processes and rival apparatus and rival inventors, engineers, manufacturers, and others to compete with Minerals Separation. Until that time arrives, therefore, the Federal Trade Commission, "re-creating, out of the elements now composing it, a new condition which shall be honestly in harmony with and not repugnant to the law" (United States v. Amer-

ican Tobacco Co., 221 U. S. 106, 187), should make explicit directions as to the amount of royalties to be charged, to the end that the exorbitant and discriminatory royalties, which are the purpose and crowning accomplishment of years of unfair methods of competition on the part of Minerals Separation, may not be perpetuated after the mere practice of such methods has been discontinued.

Following the reading of this paper at the American Mining Congress, Alfred A. Cook, legal counsel and one of the directors of Minerals Separation North American Corporation, speaking as he stated "subject to correction" by the Corporation's officials in New York, questioned my statement above that after November 6, 1923, a Minerals Separation standard licensee "who has never used any process or apparatus belonging to Minerals Separation, excepting only the process" covered by No. 835,120, then expired, would still be obligated to continue to pay royalties to Minerals Separation.

To clear up this difference regarding the plain meaning of Article 1 of Minerals Separation's standard license agreement, which unequivocally provides, without any time limitation whatsoever (in this respect unlike Minerals Separation's agreements with certain favored licensees which by their terms expressly expire November 6, 1923), that "the licensees shall pay royalties to the licensors for the use of all processes and appliances embodying all or any of the inventions described and claimed in the letters patent within this license" at the rate specified by the agreement, Mr. Cook, at my suggestion, telegraphed to New York, and on the following day received from the president of Minerals Separation North American Corporation a reply to the effect that such a licensee would not be obligated to continue to pay royalties to Minerals Separation.

Since this same official, in a letter read by Mr. Cook on the previous day, had stated that the obligation to pay royalties continued so long as the process was *used*, and since the vice-president of Minerals Separation North American Corporation had similarly testified in the Federal Trade Commission proceeding (record p. 580), I promptly expressed to Mr. Cook my grateful appreciation of this apparently magnificent concession by Minerals Separation.

Further discussion of the same point, however, promptly developed the fact that while so modifying Article 1, Minerals Separation was by no means ready to modify Article 5, which provides that "the licensees shall not directly or indirectly during the continuance of this license nor at any time after the termination thereof dispute or object to the validity of the letters patent within this license or the novelty or utility of the inventions specified therein"; and that therefore any licensee using the process now covered by No. 835,120, then expired, would be obliged to accept Minerals Separation's opinion as to whether such process was covered by any of the scores of other "letters patent within this license", and would be prevented by Article 5 above quoted from ever "disputing or objecting" to Minerals Separation's

opinion on this subject. The record in the Federal Trade Commission proceeding abounds in expressions of Minerals Separation's opinion to the effect that every conceivable process of flotation is covered by one or another of its scores of patents, so that so long as Article 5 stands, any licensee who after November 6, 1923, ventures to discontinue paying to Minerals Separation full quarterly royalties upon the basis specified in his license agreement may be sued by Minerals Separation for alleged infringement of any of its scores of other patents, and by the provisions of Article 5 will be estopped from ever disputing or objecting to the validity of such patent or the novelty or utility of the alleged invention specified therein.

This apparently magnificent concession by Minerals Separation, with which Mr. Cook, by his gallant and chivalrous manner, succeeded in raising high hopes among his listeners at the Convention, thus proved to be entirely illusory.

That every other restraint above described, imposed by Minerals Separation's standard license agreement, was in effect eternal because of the ingenious provisions above described for extending the life of the agreement was not disputed by Mr. Cook.

Platinum

By S. Skowronski

*The most valuable of the industrial metals in the world today are those comprising what is known as the platinum group. These metals, all of which are allied with platinum in their chemical and physical properties, are associated with platinum in native ores or deposits found principally in Russia and in the Republic of Colombia. On September 18 the quotations for these metals per troy ounce, were as follows: platinum, \$115; palladium, \$105; iridium, \$375; ruthenium, \$210; and osmium, \$62. In the electrolytic refining of copper and nickel, platinum and palladium have been found in large enough quantities to warrant the recovery of these metals. Platinum was first discovered in Colombia, in about 1735, and on account of its white silvery appearance, was called 'platina', the diminutive form of the Spanish 'plata' meaning 'silver'. Owing to the high specific gravity of platinum, it being a little higher than gold, it was first used in the adulteration of gold, and on this account, the Spanish government at one time ordered all of the metal on hand thrown into the sea, and would not allow the exportation of the metal from South America. In 1819 the great deposits of the platinum metals in the Ural mountains of Russia were discovered, and since that time Russia has been the great exporter of platinum metals.

Platinum was formerly extensively used for the evaporation of sulphuric acid in sulphuric acid works, large pans of platinum being used for that purpose. Finely divided platinum possesses the remarkable property of promoting or hastening chemical changes without under-

going any decomposition, acting, as what is known to chemists, as a catalizer.

Owing to its high melting point and resistance to corrosion and fumes, platinum was formerly used in the construction of small electric-resistance furnaces and heating elements for laboratory work; also for the manufacture of contact points, in various types of ignition systems, magnetos, and spark coils, but owing to the continued increase in the price of the metal, substitutes are now being used. The most important use for platinum is in dental work and formerly fully one-third of the total production of the metal was used for that purpose. Platinum being non-corrosive and not affected by the acids of the mouth, is an ideal metal for the construction of pins, pivots, and anchors of artificial teeth and other dental work.

Platinum is indispensable for scientific purposes, and the increasing use of the metals in jewelry has, at times, been sharply criticized by scientific men, a quotation from one of the scientific journals being as follows: "From the scientific point of view, much regret is felt that platinum has found employment in the jewelry trade. Silver or gold is much better adapted to the production of attractive ornaments and is more beautiful than the grayish-white of platinum, while, of course, neither metal has the high fusing point and the resistance to acids which makes platinum indispensable in science and the industrial arts. The scientific and technical world needs all the platinum that can be obtained."

The jewelry trade in turn attempts to justify the use of platinum in jewelry in the following article copied from a trade paper: "Platinum is the metal par excellence for fine and delicate jewelry. First, because its brilliant white color enables the jeweler to obtain beautiful effects in the setting of diamonds, which cannot be obtained with gold, owing to its yellow color. Secondly, on account of its malleability, ductility, rigidity, and tenacity, the most delicate and intricate designs are possible with a surprisingly small amount of metal. Lastly, because jewelry made of platinum will retain stones in its settings without the heavy beading required in gold settings and will not tarnish or oxidize from exposure to air, fumes, or acids, or when worn on the body. This combination of qualities does not exist in any other known precious metal and has made possible most of the great advance in the jewelry art of recent years."

In the electrolytic refining of copper, the platinum and palladium present in the original crude or blister copper, concentrate to the very end of the process and are recovered from the electrolyte of the Wohlwill process used in the electrolysis of gold. It is only within the past ten years that the copper refineries have been recovering the platinum and palladium present in the copper. Formerly it accumulated and was shipped in the gold bars and was lost to the plants. While the total amount of platinum metals recovered in the refineries is small, it is practically the only source of these important metals which this country has, as the native ores or platinum sands furnish only 700 oz. of crude metals yearly.

THE MINE, THE MILL, AND THE OFFICES

Milling Practice at the Benguet Consolidated Mine—II

Details of Practice

By C. M. Eye and M. F. Dodd

BREAKING. As most of the ore when it comes from the mine is sufficiently fine to pass the grizzly-bars, it is only necessary to operate the crusher at intervals, the total running time amounting to but a few hours daily. It is now driven from the 10-hp. motor, at a speed of 280 r.p.m. through the medium of a short-centre drive, which is more satisfactory than the former long drive.

DRY ELEVATING AND WASHING. The feeder, elevator, and trommel, operated as a unit from a line-shaft driven by a 5-hp. motor, work efficiently except when the ore comes from the mine wet and sticky. Then trouble is experienced through its hanging up over the feeder, packing in the buckets of the elevator, and (when much clay is present) balling up in the washer and passing in chunks to the bin. Ordinarily, however, the service is satisfactory. The 12-in. rubber belt of the elevator is protected by the backs of the buckets, which form a continuous line. The buckets, 10 in. wide, fabricated of No. 12 gauge steel, show little wear after long usage. The principal wear occurs on the screen covering of the trommel, after the addition of solution, and especially toward the lower end, after the removal of the most of the fine. Steel-wire screens with rectangular openings were first tried, but a set lasted only from four to five weeks. Punched-steel screens with elliptical openings, $\frac{1}{4}$ by $\frac{3}{4}$ in., were substituted with better results. The longer dimension of the holes is at right angles to the axis of the trommel.

STAMPING. As previously noted, the ten stamps are driven by a back-gear motor. The drive, through the

medium of a 14-in. belt, is nearly horizontal, with a tightener pulley on the upper side. A spare 25-hp. motor of the same kind is set directly back of the one ordinarily used, so that, in case of necessity, the change to it can be made quickly. This ensures practically continuous stamp-operation, which was more important when all the material had to pass the stamps than now, when they have to crush the coarse material only. The drop is now 7.5 in., 106 times per minute. This is a greater drop than was formerly necessary. Then the indicated horsepower at the motor was about 17.5; it is somewhat greater now. Excessive splash is prevented by hanging a light steel plate from the top of each screen-frame. Goldfield guides with removable split shells are used satisfactorily.

CLASSIFICATION. The drag-classifier, receiving the stamped product, consists of a five-ply balata belt 8 in. wide with flights of 2-in. angle-iron bolted to it at 12-in. intervals, working over a head pulley of 16 in. diameter and a tail pulley of 26 in., in a wooden tank, 26 in. wide, 24 in. deep at the lower end, and 14 ft. long. It is driven at the head end, by belt and spur-gear, giving a belt-travel of 28 ft. per minute. As none of the bearings are submerged, no stuffing-boxes are necessary. Every fourth flight is 22 in. long, the rest are 18 in., giving a head product of less moisture than if the flights were of equal length. This machine, built on the ground, has given good service over a period of years, one belt having lasted three years. It may be termed a roughing-classifier, for removing the bulk of the coarse product for direct delivery to the tube-mill.

The primary Dorr classifier performs a somewhat similar function on the portion of the pulp by-passing the stamps, by removing a coarse product for tube-milling, and passing the finer to the two secondary classifiers, working in closed circuit with the grinding-mills, and furnishing the final finished product for treatment. This product, on which frequent screen-tests are made, usually has about 5% coarser than 100, and only 10% coarser than 200-mesh. Assays on the pulp at this point show that about 60% of the precious metals is dissolved. The degree of dilution is usually about six of solution to one of solid.

FINE GRINDING. This is done in two Dewco tube-mills identical in every respect, except as to length; the newer one being two feet shorter than the other. It was thought that the new mill, working on the softer material coming directly from the washing system, would finish it as effectively as the longer mill, working on the stamped material. This does not appear to be the case, as there is a greater proportion of oversize in its discharge. There is a direct saving in power, of course, as this mill operates with a 40-hp. motor instead of a 50, but it is the opinion that 10 ft. is the proper length for a 6-ft. mill on this ore. The new mill is driven by a 14-in. belt without a friction-clutch, from a motor of high starting-torque. This has not proved so satisfactory in practice as the drive on the older mill from an ordinary motor by a friction-clutch, as this enables full speed to be attained on the motor before the mill is engaged. Both drives are nearly horizontal. A so-called boltless type of shell-liner is used, requiring no bolting through the shell of the mill. Each circle, 6 in. long, is complete in itself, and consists of six segments, four with plain radial ends, and two with plain ends at one extremity and a lug arrangement at the other, whereby, after a circle is in place, it can be expanded tightly against the inside of the shell, by means of a 1-in. steel bolt. Steel shims of various thickness are placed in the plain joints to give better bearings and to adjust the circle. On the circles that include the man-hole frame, which is 18 in. long, one of the plain segments is shorter than the others by the width of the frame. When the liners are in place, there is presented a series of pockets on the inner surface of the mill, which fill quickly with pebbles and thus form a superior wearing-surface. These pockets just about take a No. 5 flint pebble nicely. The total depth of the liners, with the back of one inch, is six inches, so the effective diameter of the mill when lined is five feet. The total weight of shell-liners sufficient to line both mills is ten tons. A set of ordinary hard white-iron lasts from five to seven months, the weight of the discarded liners being about 55% of that at the beginning. The greater part of the wear is in the pebble-filling, and when the liners wear down to the point where the filling does not hold well, it proceeds more rapidly. When it has reached the bolts and lugs and these are worn off, the lining is held only by the 'set' of the pebbles and fine ore that has cemented every crevice. Usually this is sufficient to hold the circles in place until the back is nearly reached, when the liners

may go out entirely. If one particular ring happens to wear faster than the rest, it is possible to replace worn segments with others recovered from former linings, but the point is soon reached where the whole set must be replaced. This is done quickly, the entire change usually requiring not to exceed ten hours, the removal of the old segments taking more time than the placing of the new ones. An effort is being made to increase the life of the liners without too great increase of cost by using liners of higher-grade material than white-iron. No figures are as yet available on this, however.

The heads of the mills are lined with two circles of segments constituting 'inner' and 'outer' head-liners, any segment of either circle being removable independent of the others or of the shell-liners. As a rule, however, an entire circle is replaced at one time. These are held by bolts through the heads in the usual way. Only hard white-iron has been used for this as yet. The first mill was equipped with a scoop-feeder with a 5-ft. radial sweep, rendered necessary by reason of the classifier working alongside in closed circuit, but since the classifiers have been raised to the floor above, enclosed spiral feeders are used to great advantage. The long-sweep scoop-feeder never was satisfactory. The speed of the mills is maintained at about 27 r.p.m. for the best results. Pebbles are fed as a rule through the head end, since the spiral feeders are used; formerly the bulk of the pebbles was fed through the discharge end, being carried into the mill by the reverse spiral liner at that end. The larger pebbles and mine-rock were charged at intervals through the man-hole, and any large rock is still so charged. The present practice is to charge No. 5 flint pebbles in this manner, after a new lining has been put in, sufficient in quantity to fill the pockets of the lining, and then to add smaller flint pebbles (No. 3 and 4) in excess of the mine-rock until a good grinding charge is secured; thereafter, a mixture of mine-rock and flint pebbles in the proportion of 3:1 is added daily as needed. The pebble charge is maintained at about two inches above the centre line of the mill, to give the best grinding with the lowest power consumption. If at any time the ammeter on the motor shows a rapid drop in power consumed, with an increase of coarse at the discharge of the mill, the proportion of flint pebbles to mine-rock is at once increased.

By using rock, selected from the harder portions of the ore, and costing very little to prepare, a considerable economy in pebbles is effected, without excessive liner wear or decrease in grinding efficiency. Imported pebbles cost about \$75, delivered at the mill, while mine-rock costs but \$2 or \$3 per ton to prepare, and has the added advantage that it contains gold and silver, and therefore adds to the yield of bullion. Were the rock harder, it might be possible to eliminate the use of flint entirely, but experience gained during the War, when flint pebbles were very hard to obtain, showed that a good grinding charge could not be maintained with mine-rock alone and that under these conditions, the wear of the liners was abnormally great.

No gratings are used at the discharge end of the mills,

BETWEEN THE MINE AND THE MILL

as no trouble is experienced with pebbles or coarse rock working out; the reverse-spiral liner evidently prevents this. As has been mentioned, practically all the cyanide is introduced at the head of the mills, where a constant drip of saturated solution is maintained. At times it is necessary to add some lime also at this point, but only in case of an unusual decrease in alkalinity.

WET ELEVATING. The two elevators handling pulp to the classifiers are practically identical in construction and operation. Since they replaced the two formerly in use, the material in these was used in their construction. They consist essentially of 12-in. eight-ply Silverton rubber belts working over 26-in. head pulleys and 24-in. boot pulleys, at a speed of 350 ft. per minute, the drive being from the top, as usual. The boot shaft, of 2.5 in. diameter, is carried in take-up bearings, and has stuffing-boxes to prevent leakage. The head shaft, 3.5 in. diam. and carried in plain boxes, carries an overhang pulley, by means of which the elevator is driven without the use of gearing. The pressed-steel buckets, spaced at 12-in. centres, are 4.5 by 5.5 by 8 in. No trouble is experienced with the packing of material in the buckets, which clear themselves beautifully at the discharge. The lift is about 25 ft. vertical, and either elevator has sufficient capacity to handle, if necessary, all the material to be lifted. The wear and tear is not great, but, naturally, some shut-downs for repairs are unavoidable. Taken all in all, elevators of this type would seem to offer the best means of elevating finely ground pulp of the character handled at this plant.

PRIMARY THICKENING. As has been noted, this is done in two thickeners, one preceding and one following the first agitator. The overflow from the first, or 30-ft. thickener, furnishes about 75% of the flow for precipitation during normal operations. As noted, there is no dilution of the flow to the second, or 25-ft. thickener; so the grade of the off-coming solution is about the same as that from the first thickener. In both, there is a sheet-iron baffle-ring projecting a foot or so above the surface of the charge at about 6 in. from the edge, which holds

back the froth resulting from the use of lime. The overflow from both goes by gravity to the clarifier, but on occasion it can be sent by gravity direct to the zinc-boxes. As a rule, however, it has to be clarified to remove very fine slime held in suspension.

AGITATION. The detail of the first agitation has already been described; it may be well, however, to refer more fully to the action in the Trent machine. The pulp and solution, with an admixture of atmospheric air, entering the arms through the central opening and distributing head at the bottom, is forced out through the nozzles, pointing downward and backward at an angle of 50° from the horizontal, the pressure causing the mechanism to revolve. The pulp discharging over the bottom of the vat in annular circles of equal area, mixes thoroughly with the pulp in the vat, and through the circulation maintained as heretofore described, is slowly and gently carried toward the top of the charge, at all times intimately in contact with air. There is no violent or boiling action; simply a slow upward movement, with ebullition of small air-bubbles on the surface. When in action, the charge has the appearance of simmering. When the ratio of solution to pulp is kept at about 2:1, there is practically no settling of the larger or heavier particles; in other words, there is practically no accumulation at the bottom of the vat. The revolving unit is carried on a ball-bearing placed above the vat; and the whole can be lifted bodily in case it is necessary for repairs. The main difficulty in the internal operation arises from accumulation of wood-pulp, etc., in the nozzles, but when the incoming pulp is carefully screened, as it usually is, this is not so pronounced. The wear of the distributing mechanism is not great. As is usual with this class of machine, the greatest trouble comes from the centrifugal pump. As the pump used is one specially designed for the work, with hard-iron replaceable liners, extra-long gland and boxes, etc., the trouble is minimized. The greatest wear takes place on the runner and shaft, but the latter is made extra long and reversible, end for end. A shaft and runner last about eight months. The pump, driven

at 600 r.p.m. from a 5-hp. motor by a horizontal belt-drive, actually consumes about 4.2 hp. normally. Care must be taken to keep the pump well packed to prevent undue leakage.

After protracted shut-downs, no trouble is experienced in getting the agitator under way. When it becomes necessary to lift the mechanism, the charge is pumped out to about one-half, the mechanism lifted above the surface, and lowered again over the upward projection of the inlet pipe, which serves as a guide in operation. Altogether, this agitator has given very satisfactory service.

The second and third agitation operations are conducted as noted, in Dorr combined mechanical and air machines. The air for the central lift is furnished by the 10 by 8-in. compressor mentioned, at a pressure of about 18 lb. The machine is too well known to require detailed description here. The distinctive feature at this plant is the device for obtaining pulp transfer; it consists of a shallow pan, several feet long, with the top set just above the surface of the charge and connecting with a pipe leading through the side of the vat. The ends of the distributing-arms pass above this pan and discharge into it during the period of passage of whatever pulp may be flowing from them. It is obvious that the flow of pulp must be regulated so that the amount leaving the ends of the arms during such period is equal to the amount coming in. It has not been found difficult in practice to so regulate the discharge, and the arrangement has the advantage of ensuring at least one complete circuit for any given particle of ore before leaving the vat.

SECONDARY THICKENING AND DECONTAMINATION. The four secondary thickeners are set in the form of a square, with the three diaphragm-pumps near the centre, side by side. From the pumps, launders run to the last agitator and the last two thickeners respectively, while they are connected in the same order with the discharges of the first, second, and third of the thickener series. The diluting solution, of course, is added in the launders and thoroughly mixed with the pulp before entering the vats indicated. The thickeners and pumps are driven from one line-shaft, in turn driven by a 3-hp. motor. The pumps are furnished with long connecting-rods and adjustable eccentrics, and each has a pet-cock below the diaphragm for the admission of air in regulating the amount of pulp lifted. Considerable trouble has at times been experienced by reason of diaphragms of poor quality, but with good ones, the normal life is from two weeks to a month. There is little wear or expense aside from this. The actual lift is short (probably not more than six feet), as the static head of the charge in the thickener is sufficient to life the pulp to within a few feet of the top of the vat, as is shown by the discharge from the last thickener of the series. In fact, where conditions permit it, better discharge can be had from a thickener by means of the static head alone than where lifting is necessary. Where counter-current washing is used, it is not practicable, however, as it is of greater importance to secure gravity

flow of the counter-current solution by arranging the vats as they are here arranged, with a two-foot drop between vats from the last to the first, or six feet of drop in all. The arrangement here used permits of varying the application of the washing solutions to fit the needs of the case.

The pulp as it leaves the last thickener has a specific gravity of from 1.3 to 1.4, the thickening in the other tanks being carried as nearly as possible to the same degree.

REPLACEMENT. The three Trent replacers in use are identical in size and equipment, and the action in each is the same. This action has been already described with reference to the first, interposed in the treatment in advance of the second agitation. Receiving as it does the pulp that has been diluted with a low-grade gold solution from the overflow of the others, the overflow from it is of sufficient grade to be returned to storage. Since all three take barren solution in the pump-suctions, the cyanide content is practically the same in the overflows from them all. The amount of solution introduced at the bottom is kept slightly in excess of the amount drawn off from the pump-discharge for passing onward with the pulp, which results in a slight upward movement of solution in the charge; not enough to hinder the ore particles from settling, but sufficient to prevent any downward movement of the solution coming in with the pulp at the top and to secure an overflow slightly in excess of the amount of such solution. Of course, it is impossible to prevent diffusion to a certain extent, and the slight upward movement in the charge results in the fine slime rising to near the top of the charge. The line of demarkation between slime and clear solution is usually within an inch or two of the top. There seems to be no advantage in attempting to carry it lower, and there may be less diffusion in this case.

The use of a tapered vat is of decided advantage, as it gives increased settling-area, with decrease of the upward movement as the top is approached, with decreased power consumption, owing to a smaller machine being used than would be necessary in a straight vat, and with more concentrated and cleaner work at the bottom. Such a vat is just as easy to build as a regular straight-sided vat, and has been just as easy to maintain.

The remarks anent pump operation under the heading of agitation, apply with equal force to the circulation maintained in replacement, except that in this case, the pumps are smaller and are operated at considerably less speed. They are of the same type and make, with solution-protected glands, etc., and are driven individually from motors by belt. While the motors are each of five horse-power to provide extra power in case of emergency, the actual indicated power delivered is considerably less than four horse-power as a rule, for each one. As regards relative position, the three replacers are set in a row, the top of the first being two feet higher than that of the other two, which, as remarked, can be used in series, in parallel, or separately, as occasion may require.

FILTERING. Under this head is included the final thick-

ening, as this is but a preliminary operation in preparing the pulp for the filter, removing at the same time a portion of the incoming solution from the last replacer. This thickener, like the last of the regular series, discharges by static head. It serves for storage and as a means of obtaining a steady feed to the Oliver filter, on which the final solution-wash and the only wash-water is applied. The effluent solution from these washes, low in gold and cyanide, is raised by a centrifugal pump to a separate storage at the head of the mill for use in the washing-plant. The amount of water-wash here applied is regulated by the amount that the entire solution-circuit will stand without running solution to waste. As this is quite limited, it is essential to apply the water-wash in the most efficient manner, to obtain the maximum of washing with the minimum amount of water.

Since lime is used, it is necessary to give the filter an acid wash at times. This is done by emptying the tank of the filter and then running on dilute hydrochloric acid through the spray-pipes with the vacuum maintained, whereby the acid is drawn through the filter and returned to the tank above the filter, where the required strength of acid is maintained by further additions. This practice has eliminated much of the scrubbing, has kept the pipes clear of lime incrustations, and has saved much of the wear on the filter.

The use of this filter, which is of the latest type and an unusually large single unit, is apparently justified by the resultant saving in dissolved metal otherwise unobtainable as the plant stood, as well as by the increased treatment made possible in the preceding units. Its operation has been considerably hindered by shortage of power, but it is hoped that data based on more extended and steady operation may soon be available.

PRECIPITATION. The pregnant solution from the primary thickening is divided as equally as possible among the 12 lines of compartments, the head ones being filled with excelsior and the others with zinc-shaving. It has been found that by the use of excelsior in this way, a final clarification is obtained, and if there is any tendency for lime-salts to precipitate, they deposit on the filaments of the excelsior instead of on the zinc. Several times each month the excelsior is shaken up and washed thoroughly, the compartments containing it washed out, and the excelsior replaced.

Lead acetate to the extent of a few pounds per day is added to the zinc-boxes to ensure good work. Formerly this was added entirely in the first compartments containing zinc, but now it is added all down the line, a little to each compartment. This has resulted in a decided improvement in the precipitation. It may be remarked here that there is no addition of lead-salts at any other point in the treatment, except that the used cupels from the assay-office are fed in the tube-mills from time to time. There seems to be practically no formation of soluble sulphides at any stage of the treatment.

The zinc is prepared in the usual way by cutting from sheets on a lathe, but it is not added daily, nor are the compartments, once packed after a clean-up, disturbed

until the next, unless there should be some special reason for it. The zinc filaments, cut one eight-hundredths of an inch in thickness, drop into a box one by two feet, and one foot deep, until it is filled; they are then pressed down into a pad about two inches thick, and removed and stored until needed. When used, these pads of filament are laid in the boxes in pairs, alternately lengthwise and crosswise, until the compartment is filled.

Normally, something over 400 tons of solution undergoes precipitation in 24 hours. The effective space of the compartments containing zinc is about 430 cubic feet, which gives practically one ton of flow per cubic foot per 24 hours, as established by Alfred James. The grade at the head is usually between \$3 and \$4 per ton and often more, while that at the foot is reduced to a few cents. The actual value precipitated per day is quite accurately determined by means of the method of solution measurement previously described, in conjunction with the daily assays of head and foot solution. The method mentioned was developed at the Tom Reed mill by Mr. Jones, superintendent.

CLEAN-UP. These are made bi-monthly on the first and fifteenth. The procedure is as follows: The solution is shut-off from a line of compartments and an iron box, two by four feet, and one foot deep is placed crosswise of the line and is half-filled with clear solution. Two wooden trays, each 22 by 20 in., and 9 in. deep, with a 20-mesh steel screen on the bottom, are suspended in this box. The zinc in the first compartment is first shaken thoroughly in the solution filling the compartment and then transferred to the trays for final washing. The trays are given a jiggling motion, which separates the precipitate and 'shorts' from the longer zinc. These accumulate in the box, below the trays. The contents of the compartment are washed out through a plug in the side into a launder leading to the refining-room, the compartment being then thoroughly washed with fresh solution and the supporting screen replaced. The coarse zinc remaining in the trays is then replaced, and the second compartment handled similarly, except that the zinc remaining in the trays from this one is added to that in the first compartment until it is filled. Any left-over is placed on the screen of the second. In the following compartments, the zinc is washed in the compartment and moved up. Each compartment when empty of zinc is discharged into the launder and washed thoroughly before replacing the supporting screen and introducing the zinc. After all the old zinc has been moved forward, the space remaining is filled with pads of new zinc, placed as noted. This procedure was adopted after trying many other methods, and has resulted in the production of a minimum of 'shorts' and a great saving of time and labor.

All the material carried by launder to the refinery passes onto a 30-mesh steel screen. Any too coarse to pass is added to that remaining in the iron box mentioned, after the latter has been washed by decantation into the launder. This accumulation of 'shorts' is placed in successive charges in a barrel for cleaning. This barrel, made on the ground from a 60-gal. oil-drum, is lined with

steel plate and has a man-hole and cover, and on the ends it has flanges into which are screwed 2-in. pipes serving as trunnion-bearings. By means of a small pipe the solution is introduced through one of these trunnions in a steady stream during grinding, and flows out through the same trunnion, the other trunnion being closed. Grinding is carried to the point where this solution comes off practically clear, when the remaining zinc is returned to the upper compartments. With the product so treated at the principal clean-up in the first of the month, a charge of about 75 lb. of small flint pebbles is carried in the barrel, in order to get as close a clean-up as possible. At the mid-monthly clean-up, this pebble charge is omitted. It seldom happens that there is sufficient accumulation of 'shorts' to require acid treatment to get rid of it, because the boxes will take a considerable amount of the cleaned short zinc without becoming clogged.

REFINING. From the accumulating tank, the product is drawn by a rotary pump into a 20-frame clean-up press, the pump moving the clear solution back to the head of one line of zinc-boxes. That first drawn off from the top of the tank is practically free from zinc, but is low-grade. After being dried as nearly as possible by means of compressed air, this is discharged and placed in pans and dried in an oven to a point short of dusting; it is then pulverized and held for mixing with the higher-grade product to follow. This product is handled in much the same way, except that it is heated to redness in the oven. After cooling, it is carefully pulverized to minimize dusting and thoroughly mixed with the somewhat damp low-grade product. After putting through a $\frac{1}{2}$ -in. screen this mixture is weighed, mixed with flux, and melted in successive charges in two Case oil-burning furnaces, in No. 125 graphite pots. When fusion is complete, each charge is poured by tipping the furnace, the first 80% discharging into a pit filled with water and containing a suspended wire basket, and the remaining 20% into a conical mold. The granulated slag from the pit is collected, dried, crushed, and ground, and later concentrated on a small table for removal of fine gold and matte, then sealed in 5-gal. oil-cans and held for subsequent shipment to a smelter. When sufficiently cool to handle, the cones from the molds are dumped, the button of metal, and any matte there may be, is removed, and the remaining slag crushed and added (while still hot, if possible) to the succeeding charges. The metal is held until the run is finished and then re-melted into bars of about 200 oz. Troy. It assays ordinarily about 600 fine in gold and 250 in silver.

When sufficient matte has accumulated to make a charge, it is reduced in one of the Case furnaces, using for this purpose a crucible nearing the end of its service, thin at the top, but still having a good bottom. The charge is made up of finely divided matte, assay-slag, and flux, well mixed, and is brought to a high degree of heat; then scrap-iron is stirred in until no more will be absorbed. The heat is raised as high as possible and the charge poured into a conical mold. After cooling, the matte, greatly reduced in value, is broken off, crushed,

and packed separately for shipment while the resultant bullion is melted into bars for separate shipment. This bullion usually assays about 250 fine in gold and 450 in silver and contains considerable lead, the proportion depending, of course, on the quantity and character of the assay-slag used. By weight this low-grade bullion is about 15% of that of the regular bullion. All the bullion goes by mail to the Mint at San Francisco, unless there is a demand for it at a premium in the local market.

PREPARATION OF LIME. Burned lime is furnished from local sources at about \$20 per metric ton delivered at the head of the tram. Owing to climatic conditions, it is not practicable to burn and handle lime except in the dry season, so a supply adequate for the year is received during these months, transferred over the tramway to the mill in sacks, slaked, and run into open pits as hydrated lime. When a pit is filled the surface is covered with a layer of sand, which maintains the lime in the form of a thick paste until needed. When a pit is opened, the contents are removed as required by cutting from the edge of the bed, usually about four feet deep, so as to expose as little surface as possible to the air. It is added to the mixers in the form mentioned, and in them emulsifies quickly and thoroughly, while any particles of unburned lime or foreign matter are ground by the rollers of the mixers, leaving no accumulation in the pans. The mixers, built on the ground, consist essentially of steel pans, four feet in diameter by two feet high, with a 2-in. discharge-pipe set 10 in. above the bottom, and two rollers, each 6 by 10 in. on radiating arms from a central upright shaft, driven from overhead by bevel-gearing. They take very little power to operate and have proved satisfactory. About ten pounds of lime per ton of ore is required to maintain proper protective alkalinity, which tests at about 0.28 in the zinc-boxes.

SAMPLING. As previously noted, no sampling is done on the ore as it enters the mill except to determine the moisture. At the period when all the ore was stamped, numerous trials were made on sampling the stream of ore through the feeders, but the results were always so erratic as to be of no value, and the method involved a great deal of labor. Sampling the discharge from the mortars was also tried, with a correction for the estimated amount of value dissolved in stamping. The results from this, while not so erratic as from the former method, were not close enough to be dependable. With the introduction of washing with weak solution, the problem was further complicated, so the present practice is to take frequent pulp and solution samples at various points of the treatment, measure the flow of the solution and estimate the incoming value as closely as possible. The tipping automatic sampler mentioned was soon discarded as being unreliable, and careful tailing-sampling by hand was substituted. Careful testing is done on each shift in the mill for cyanide and protective alkali at various points.

The total consumption of cyanide (99.5% NaCN) in the treatment is about one pound per ton of ore treated. The major portion of the chemical loss appears to be in the tube-milling.

Moving Sacramento Hill

One of the most important mining projects in progress in the South-West today is the razing of Sacramento Hill at Bisbee, by the Copper Queen branch of the Phelps Dodge Corporation, to recover approximately 25,000,000

tons of low-grade copper ore that is under the mountain. Within 20 years this sentinel of the Warren district will have been entirely obliterated and the bulk of its contents sent to the smelter or mill. About a billion pounds of copper will have been recovered in the process.

Since work was started in 1917, more than 5,500,000

SACRAMENTO HILL, AT BISBEE, IN OCTOBER 1917

SAME VIEW AS ABOVE, PHOTOGRAPH IN OCTOBER 1920

cu. yd. of material has been moved. When the work is finished there will be, in place of the hill, two pits, one about 1500 ft. diam. and 420 ft. deep, and the other about 2200 by 1500 ft., and 440 ft. deep. These data were obtained from exploration by churn-drilling.

The total amount of material to be removed is about 40,000,000 cu. yd., slightly less than one-third of which by volume will be ore. It is estimated that it will take 16 years to fully complete the work. Seven steam-shovels are employed in the operation, and are served by 15 'dinkey' locomotives, hauling trains of four to six dump-cars. Until the recent reduction in operations was put into effect, the company was handling about 225,000 cu. yd. per month. The hill is being reduced by means of horizontal benches which are 60, 45, and 35 ft. in height. About 16 miles of railroad track was laid to connect these benches with the waste dumps and the concentrator.

The ore from the hill will be divided into three classes. All above $3\frac{1}{2}\%$ copper will be sent directly to the smelter; ore averaging between 1% and $3\frac{1}{2}\%$ will be sent to the concentrator; and all ore below 1% copper will be treated by the heap-leaching process. The concentrator and crushing plant are now under construction. The ratio of concentration will be about 4:1, and the concentrate will average between 7 and 8% copper.

The razing of Sacramento hill necessitated demolishing the former power plant of the Copper Queen, which was situated at one side of the hill. The company has completed the construction of a power-line from the smelter at Douglas to the mines at Bisbee, carrying 4000 kw. An auxiliary plant of Diesel engines, two of 1000 hp. and two of 2000 hp., have been installed for emergency use. The work will necessitate also the abandonment of the Sacramento shaft, the present main hoisting shaft for all underground operations, and the substitution of the Dallas shaft for this purpose.

THE QUINCY MINING CO. recently placed in operation its new Nordberg hoist at No. 2 shaft. It is the largest hoist in the world. It has a winding capacity of 10,000 ft. of $1\frac{1}{2}$ -in. rope reaching down an inclined shaft to a vertical depth of 6600 ft. When winding the rope down the second cone of the drum, it has a capacity of 13,300 ft. reaching to a vertical depth of 8600 ft. The hoist operates in balance, raising a load of 20,000 lb. per trip, and is designed for a rope-speed of 3200 ft. per minute. The drum is of the clindo-conical type which is so familiar in the Lake Superior copper district. There are eight impulses per revolution and together with the great mass of the drum, which weighs 516,000 lb. without the shaft, practically all pulsation in the rope is eliminated. The drum is built up of 48 sections securely bolted together and thoroughly trussed within. This arrangement prevents any deflection of the drum-shaft. The hoist is fully protected by an improved safety stop, whereby the throttle-valve is automatically closed as the skip approaches the landing. In case of overwinding, the engine is also reversed and the brakes are applied automatically. The hoist cannot be started in the wrong direction. Over-

speed is prevented by a speed governor which controls the cut-off cams of the valve-gear. The total weight of the engine with condensing equipment is 1,765,000 lb. The engine covers a floor space of 60 by 54 ft. and stands 60 ft. high from the bottom of the foundation to the top of the drum. The foundation under the hoist and condensing equipment contains 3000 yards of concrete. The weight of the skip is 10,000 lb. The weight of the 10,000 ft. of rope is 41,500 lb. The time required for one trip of 10,000 ft. is 4 min. 8 sec. The hoist is housed in a concrete and steel reinforced structure.

Washing Coal

The benefits that may be derived from coal-washers is illustrated by the following instances cited by the U. S. Bureau of Mines. A coal-mining company in the State of Washington for many years has been discharging sludge into a pile near the mine, which the company's engineer recently estimated at 150,000 tons. Engineers for the Bureau took large samples of this material and made washing experiments on a coal-washing table. It was found that the ash content could be reduced from approximately 30 down to 17%, with a recovery of about 75% of the coal. As a result of these tests and the recommendations made by the engineers, the owners of the mine are erecting a washing-plant equipped with five tables for treating the entire pile of sludge. The material in this pile now has a recoverable value of \$2 per ton, or a total value of \$225,000. As a further example, it was found in a study just concluded at the plant of another coal company that the raw nut-coal contained 24% ash. After washing in a jig, the washed coal was found to contain 23% ash, and 15% of the feed was discharged as a washery refuse. It was decided to study the action of the jig, using the improved float-and-sink test as a control. Float-and-sink tests, using 1.55 specific gravity zinc-chloride solution, showed that 81% of the feed to the jig floated with an ash content of 14%; 82% of the washed coal floated with an ash content of 14.9%; and 62% of the refuse floated with an ash content of 16%. These results indicate that the washed coal was improved by only 1% decrease in ash, and the good coal lost in the refuse amount to over 9% of the feed or 11% of the total good coal in the feed. After several days experimenting with the jig in which the length of stroke was gradually increased from $2\frac{3}{8}$ in. up to $3\frac{7}{8}$ in. and the rate of feed and refuse discharge properly determined and adjusted, the following improvements were observed: The ash in the washed coal was reduced to 16%, with a recovery of 86%; 92% of the washed coal and 25% of the refuse floated on a 1.55 solution, the loss of good coal in the refuse being reduced from 9.3% to 3.5% of the feed. Since approximately 250 tons per day is washed on this jig, the saving effected amounts to about 17 tons per day, which, at \$4 per ton, is worth \$68. Services of two men formerly employed to pick the rock out of the washed coal were also dispensed with, thereby affecting a further saving of \$13.60 per day, or at the rate of 6 cents per ton of coal treated.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

EXPLOSIVES PLANT UNDER CONSTRUCTION.—NEW VEIN FOUND AT PIONEER.

BISBEE.—A large plant for the manufacture of dynamite is being constructed in the San Pedro valley, about seven miles south of Benson, and will be ready for operation early next summer at the present rate of progress. The organization that is back of the project is known as the Apache Powder Co., and is reported to include many of the mining companies of the State. Practically all

PHOENIX.—Vigorous efforts will be made by members of Congress from Arizona to secure the enactment of a measure exempting patented mining claims from assessment work during the year 1921. It is asserted that many owners of mining claims, under present conditions, find it impossible to secure the necessary funds for assessment work, and that for that reason such action by Congress would be justified.

RAY.—A new vein of rich silver ore, reported to average 100 oz. per ton at the surface, has been discovered on

JACKSON, AMADOR COUNTY, CALIFORNIA

of the powder manufactured will be used by mining companies of Arizona. The plant will occupy a tract of 500 acres.

Hoisting through the Briggs shaft of the Calumet & Arizona Mining Co. was discontinued on Sunday, December 5. Operations in the mine itself will be continued, but only during the day shift, the ore being taken out through the Junction shaft. This action was taken to consolidate the work and reduce unnecessary expenditure, and will not result in the laying-off of any men. A few men will be transferred to the Junction mine. The installation of a new Sturtevant blower, capable of handling 100,000 cu. ft. of air per minute at 4-in. pressure, has been completed on the 1400-ft. level of the Briggs and it is in operation, being used partly in connection with the new ventilation system of the Briggs, and partly to supply more air to the Junction and other mines of the C. & A. company.

the property of the White Metal Mining Co. at Pioneer. The new vein parallels the famous Pioneer vein. It is to be tapped as soon as possible by a tunnel, work on which has been started from a point across the creek from the company's new mill.

CALIFORNIA

DEVELOPMENT AT ARROWHEAD RICO MINE.

UBEHEBE.—Statements made by Sol Camp, manager of the Arrowhead Rico's mine, and also disinterested persons, make it evident that the company has claims holding great possibilities and the fact that ore is being broken for shipment through Bonnie Clare, Nevada, 50 miles distant, is attracting wide attention. The Rico owns nine claims that were bought from Archie Farrington of Big Pine. A drift tunnel entered the ore-shoot at the 50-ft. point and it has been continued 25 ft. more in ore 7 ft. wide and assaying \$86 to \$100 for this width.

The average metallic content is 45% lead and 40 oz. silver. Two men in the tunnel, without stoping, have broken 80 tons of ore and there is no indication that the end of the shoot is near. This tunnel is now 80 ft. from the surface and another, which should cut the vein at a depth of 300 ft., has been driven 170 of a total of 500 ft. to the vein. An air-compressor has been bought for use in this work. The orebody is a replacement of soft readily soluble lime that is considered ideal for the existence of silver and lead. The lead is in both sulphide and carbonate form and the silver is found with both, the galena in places containing as high as 100 oz. Two men shovel four tons daily and the 80 tons has been broken with 50 lb. of powder. Fifty tons has been sacked and at the present rate of hauling three carloads can be sent to Salt Lake City monthly. It is planned to continue shipping at this rate at least until the lower tunnel can be completed. The cost of hauling to Bonnie Clare is \$15 per ton and the railroad rate will be about \$12. The company has ample funds for all purposes, according to Mr. Camp, having been financed in the East. He says the first payment on the purchase price has been made and he is confident the money for the other payments can be derived from shipments.

COLORADO

RICH ORE FOUND AT ASPEN.—MODOC CONSOLIDATED HAS NEW HOIST.

ASPEN.—Confirmation of the reported find in the Park tunnel on the Celeste claim has been secured from officials. The tunnel on November 28 exposed ore in the breast assaying 11 oz. silver and, two days later, samples taken across a 36-in. streak assayed 442 oz., 419 oz., and 51 oz. An average for the entire vein gave 150 oz. silver per ton. The vein lies in brown lime, east of the porphyry and 200 ft. deeper than the old Tourtelotte park workings and at a point 2900 ft. from the tunnel portal, in virgin territory.

CRIPPLE CREEK.—The Reva Gold Mining Co., operating the Rose Nicol company's Battle Mountain property under a long-time lease, recently extended for a 2½-year term, has found rich gold-silver ore at the tenth or 1000-ft. level. The Roosevelt tunnel traverses the Rose Nicol from west to east at an approximate depth of 2000 ft., and the Reva management plans to operate from the tunnel-level. The working force, at present about 12 men, will be increased by adding a second shift.

United Gold Mines company lessees, operating the Hardwood, are accredited with producing close to \$150,000 in the past 90 days. Settlement on the last three 30-ton cars, was as follows: \$175, \$170, and \$150 per ton, while the average net mill-return has been around \$5000 per car. This ore has been mined from a shaft 40 ft. deep with winze 21 ft. The orebody is 5 ft. between walls and not more than a couple of wagon-loads of waste has been dumped. The ore has been hoisted by windlass. The most powerful electric hoist in this district is being installed at the No. 2 or Last Dollar shaft of the Modoc Consolidated Mines Co. It was manufactured by a Cleve-

land firm and has a hoisting capacity for 2500 ft. The estimated cost installed exceeds \$35,000.

The former plant at the Gold Coin shaft, believed the most costly in this district, constructed at a cost of \$260,000, is now being dismantled and the building, a steel and pressed-brick structure in the city of Victor, will be wrecked. The hoist and compressor have been sold, it is understood, to the Portland company. The Granite Gold Mining Co. has centralized operations at the Dillon shaft, on Battle mountain. Directors of the Golden Cycle Mining & Reduction Co. have declared a two-cent dividend, \$30,000, payable December 10 to stock of record November 30. With this payment the total paid will be \$9,513,330. Cresson directors met and passed the December dividend.

Zinc ore assaying from 30 to 45% has been found and is now under development at the Riley-Murray lease on the Lilian, in Iowa gulch. Ore-bins have been erected and shipments to the Canon City plant started. A raise carried 40 ft. is reported to be in ore all the way. Keystone lessees, operating in the Sugar Loaf district, are shipping steadily to the smelter a good grade of gold-silver-lead ore.

SILVERTON.—A rich find is reported at the White Cloud mine, above Ironton. Five feet of ore exposed, with no foot-wall in sight, samples \$75 to \$108 per ton with boronite showing in the ore. Development is expected to open a strong and rich ore-shoot.

BRECKENRIDGE.—Lessees on the Brooks-Snyder, Shock hill, are shipping gold and silver ore to the A. V. smelter at Leadville. One-half ton of high-grade gold ore was shipped last week and a carload of 70-oz. ore was shipped by another set of lessees.

Horn Tunnel lessees shipped a car of silver ore to the A. V. smelter last week. The tunnel is located on a spur of Mount Guyet, near Georgia Pass. The majority of the dredging boats have suspended operations for the winter, but the boats on the Blue river below Dillon will continue.

CENTRAL CITY.—Pitchblende, the uranium ore, is reported found on the Gold Rock in the Russel district. Sinking will shortly be started for a 125-ft. lift on the Hampton mine. Operations will be continued during winter by the Rich Charter Oak company on the Jack Rabbit group in the Twelve Mile district, Gilpin county.

The Buell property is shortly to become active under a bond and lease negotiated by Denver parties.

OURAY.—The Hidden Treasure Mining Co. recently organized in Washington, headed by Benedict Crowell, has acquired machinery and equipment formerly used by the Silver Mountain Mining Co., and is installing it. The property was purchased from Mrs. Evelyn Walsh who acquired it from the estate of her father, the late Thomas F. Walsh. The consideration paid has not been made public.

TELLURIDE.—A good grade of gold-silver-lead concentrate is turned out at the Matterhorn mill of the Valley View Leasing & Mining Co., and a two-car shipment to the Durango smelter was loaded this week.

GOLDFIELD.—The Florence has stopped work on company account. The only work being done was in the south-east cross-cut on the 258-ft. level, which had reached a point 1350 ft. from the shaft. This is 300 to 400 ft. from the objective, a vein that may be the southern extension of the main ore-channel of the district. The leasing policy of the company will be continued. F. Sommer Schmidt, general manager, says: "The controlling interests in general are willing to raise money to continue the plan of development until it has been brought to a point where it will be either a success or a failure, but all of the interests are not in a position to help support the work at this particular time, and the result is, some other

financial arrangement will have to be made." The Consolidated will resume the leasing policy next year.

MONTEZUMA.—The Montezuma Silver Mines Corporation has stopped work because of adverse financial conditions, according to Edwin S. Giles, manager. Three men were employed in re-timbering the Caracas shaft.

SILVER PEAK.—The plant of the Silver Peak Chemical Co., designed to produce 25 tons of potash alum and an equal quantity of flour of sulphur daily, has been started. It cost \$200,000. The company plans to employ 40 men in the mine and mill. It is reported to have contracts for the output for 18 months. Potash alum is used largely in the motion-picture industry for drying film and in the manufacture of dye and paper. The main use for flour of sulphur is in mixtures for spraying fruit trees.

RAILROAD SPRINGS.—The Allied Mining & Milling Co. has completed a 50-ton concentrator and tests have given a product containing 50% lead and 10 to 20 oz. silver, according to David Trepp, manager. The Allied is in the Railroad Springs district, 33 miles south of Goldfield, the supply point. The plant consists of a crusher, coarse and fine grinders, and a Universal table. Water for the mill is pumped 2000 ft. in an exposed pipe and freezing prevents continuous operation during the winter. A classifier and another table will be added in the spring, according to Mr. Trepp, who says he will employ 15 or 20 miners as soon as the concentrator can be operated at capacity. There is 10,000 to 12,000 tons of ore blocked-out in the mine that should be treated at a fair profit.

KLONDYKE.—A body of silver-lead ore 70 ft. long, 10 ft. wide, and assaying \$30 is reported to have been opened at a depth of 60 ft. by the Knox Divide, which recently bought the MacNamara mine for a price said to have been \$40,000. Men who have talked with officials at the mine say the company is preparing to ship 100 tons of ore daily to Millers through Klondyke station on the Tonopah & Goldfield railroad, to which a road is to be built. These men say a compressor has been bought for use in sinking a new shaft and that the company plans development on a good scale. The ore contains equal quantities of gold and silver. Edwards and Maloney, who have a lease on the Original Klondyke, have been shipping for several months and the present rate is 30 tons daily. It is reported that they have pending a deal for the sale of their lease and the mine.

SPRUCE MOUNTAIN.—The Spruce Monarch has shipped in the last year 7464 tons of ore with a content of 21.95 oz. silver and 17.7% lead per ton, according to A. H. Elftman, a consulting engineer of Tonopah who visited the mine recently. The gross value of the ore was \$250,000 and the net value was \$112,000. There is blocked out in the mine 20,000 tons of ore assaying 20 oz. silver and 17% lead and 30,000 to 40,000 tons assaying 10 to 15% lead, according to Mr. Elftman. Shipments are being made to Salt Lake City at a rate of 30 to 50 tons daily. The Ada H. is preparing to start shipping.

UTAH

UTAH COPPER COMPANY APPEALS DECISION IN SUIT WITH POWER COMPANY.

SALT LAKE CITY.—Judge Joshua Greenwood, president of the State Public Utilities Commission of Utah, will attend the hearing at Washington, D. C., December 13, when the railroads of this State will make their final appeal before the Interstate Commerce Commission for permission to increase freight rates on coal and low-grade ores, which the Public Utilities Commission refused to grant. The case was partly heard at Salt Lake City during the early part of November, and the remainder of the hearing will consist of oral arguments.

The U. S. Bureau of Mines at the University of Utah has been designated as the 'Intermountain Experiment Station' by the Department of the Interior, according to Thomas Varley, superintendent of the local bureau. The bureau will have under its jurisdiction Montana, Wyoming, Colorado, Utah, and parts of Nevada and New Mexico. The work at the local station is principally in connection with the metallurgy and ore-dressing of lead, copper, silver, and zinc.

At a meeting of the directors of the Utah Copper Co. in New York on December 3, the regular quarterly dividend of \$1.50 per share was declared, payable December 31. This will call for the payment of \$2,436,735, and bring the year's disbursements up to \$9,746,940. On December 2 the company appealed to the Supreme Court of Utah for a review of the power contract decision made in October by the Public Utilities Commission, as a result of which the company was placed on a schedule rating for power service. This almost doubled the amount previously paid by the company to the Utah Power & Light Co. The writ has been set for hearing December 16, and other large consumers, holding special contracts, are expected to file similar petitions. It is thought that the Supreme Court will amalgamate all such hearings and set a later date for the hearing of arguments.

GOLD HILL.—The Western Utah Copper Co. is now shipping 200 tons of low-grade lead-silver-iron ore per day, according to S. M. Soupeoff, engineer for the company. A drift is being driven to the south-west on the 700-ft. level, which is expected to open additional ore in that part of the company's holdings. A cross-cut being driven on one of the upper levels is expected to reach the ore soon, and shipments will then be started from that point.

PARK CITY.—The new office building of the Judge Mining & Smelting Co., and the new bunk-house, are nearing completion and will be ready for occupancy by Christmas. The bunk-house is equipped with change-rooms and shower-baths. Conditions at the allied properties—which includes the Judge, the Daly-West, the Park Utah, and the Daly—are reported as satisfactory. For the first time in years there is a surplus of labor. More than thirty lessees are working in the mines under the supervision of W. J. Wallace, formerly in charge of operations at the company's smelter.

During the week ending November 27, the Judge companies shipped 829 tons of ore and 50 tons of premium spelter; Silver King Coalition, 453; Ontario, 580; Keystone, 365; Naildriver, 60; making a total of 2137 tons. During the month of November the total output of all mines in this district was 7694 tons.

Clarence Bamberger, assistant manager for the Ontario Silver Mining Co., reports that the property is having trouble with water. On the 2000-ft. level, while development work is gratifying and ore is being uncovered, progress is handicapped by a constantly increasing flow of water. A short time ago additional pumps were installed to handle the water from this level, but the capacity of the pumps is practically exhausted and larger pumps are now being contracted for that will solve the water problem.

EUREKA.—Development work has been resumed on the 1800 and the 2000-ft. levels of the Eagle & Blue Bell property, according to William Owen, superintendent. This work was stopped several months ago, owing to labor

now has a depth of 110 ft., and with the new equipment, a depth of 1200 to 1500 ft. can be attained.

BRITISH COLUMBIA

ORE-RECEIPTS AT TRAIL.—NEWS FROM GOLDEN.

VANCOUVER.—Through the Department of Industries, the Provincial government has granted a loan at 6% interest to finance the amalgamation of the Port Moody Rolling Mills and two small electric iron-furnaces, that at present are re-melting scrap metal. The amount of the loan is \$250,000 and the amalgamation is to be known as the B. C. Steel Works, Ltd.

STEWART.—Scott Benson, who is interested in the Tonkin group, on Fish creek, states that in an interview with R. J. Summers, Surveyor General and Acting Governor of Alaska, Mr. Summers stated that the territorial government had decided to appropriate \$15,000 for the construction of a branch road from Fish creek, following the present trail to the Lucky Boy group, and thence to the

DOME MILL, AT PORCUPINE, ONTARIO

shortage, but there is now an ample supply of good miners. Within a few months it is expected that these levels—the lowest in the mine—will be producing. The ore recently struck on the 1350 and 1550-ft. levels at the Victoria mine, owned by the same interests, is being developed. This gives four levels in the Victoria from which ore is being extracted, the other two being the 1000 and the 1200-ft. levels.

The Centennial-Eureka company has let a contract for driving a drift on the 1800-ft. level. This drift will be sent entirely through the Grand Central holdings for the purpose of reaching some of the Centennial Eureka's ground which is too far from the old workings to permit of profitable working. Two shifts will be employed in driving the drift.

Preparations are being made to re-open the deepest workings in the Bullion-Beck mine. Some 12 or 14 years ago considerable work was done on the 1300-ft. level, which is the deepest point reached by the shaft, and also on the 1500-ft. level which is reached by a winze from the 1300. John Enlund, superintendent, reports that recent developments lead him to believe that there is ore at this depth. There is some water in these deep workings, which the company is arranging to pump out.

At the Lehi Tintic property the small hoist, utilized in sinking the shaft, has been replaced by heavier equipment, and sinking has been resumed. The shaft

Tonkin group, which is its objective. Work is to be continued at the Lucky Boy group during the winter.

TRAIL.—During the week ended November 21, 10,664 tons of ore and concentrate was received at the smelter. The Consolidated M. & S. Co. mines provided 9733 tons, and the other shippers were: Bluebell, Riondel, 179 tons; Bunyan, Lake Windermere, 39; Canada Copper Corporation, Allenby, 107; Emerald, Salmo, 33; Helldiver, Lake Windermere, 36; Horn Silver, Similkameen, 93; Josie, Rossland, 164; Club Hill, Republic, 54; North Star, Kimberley, 150; Providence, Greenwood, 40; Ptarmigan, Athalmer, 4; Rambler-Cariboo, Rambler, 42; Velvet, Rossland, 23; and Whitewater, Retallack, 30. During the week the first consignment of concentrate was received from the Canada Copper Corporation; Helldiver and Bunyan appeared on the list for the first time. The Bunyan consignment was in the nature of a trial shipment; there is a large quantity of this grade of ore at the mine, and it is said to be questionable whether direct shipment can be made profitably, or whether it will be necessary to concentrate in order to work the mine. The tunnel at the Morning Star mine, near Nelson, has cut the main vein, which is 10 ft. wide and well mineralized with pyrite and chalcopyrite and carries a little gold and silver. The vein has been traced for 500 ft. on the surface.

ALICE ARM.—The Moosé Group Mining Co., Ltd., Van-

couver, has done much work in the opening up of its properties and in the construction of a permanent camp. During the summer a trail has been constructed, winter quarters built, and exploration and development pushed forward, the latter being by means of open-cuts and tunnels. There are two veins so far proved, one intersecting the other. The main vein has a width of 20 ft. The upper tunnel is in 40 ft. with the face in ore averaging about 25 oz. silver per ton. By extending the tunnel 80 ft. farther the two veins will be opened at the point of intersection. On November 1 the lower tunnel was in 21 ft. and the vein now is being cross-cut, with a showing of from 8 to 10 ft. on ore on the downward extension of the orebody. The veins occur in the so-called andesite breccia characteristic of the upper Kitsault section of Alice Arm. Gray copper ore is found with high silver content, a little galena, and a considerable amount of manganese.

MOYIE.—The Society Girl mine is among the shipping mines of the Interior. Lessees have uncovered some very rich ore and intend to continue work all winter. After working a little over three months they have taken out \$3000 worth of ore. The news of this development has been received with enthusiasm by people of the district, who have of late been more or less gloomy owing to the common report that the mines of Moyie have 'played out' never again to figure as producers.

GOLDEN.—Much is expected of the Bunyan silver-lead property situated on Bunyan mountain, near Lake Windermere. A crew of from 100 to 150 men is to be employed as soon as weather conditions permit next spring. This property recently was taken over from the owners on lease and bond, after having remained dormant for 19 years. The showings having satisfied the new operators, a 600-ft. tram was installed, connecting the working tunnel and the new ore-bins. Motor-trucks have been imported to transport the ore from the bins to the nearest rail point and an early shipment is to be made to the Trail smelter. Mining continues active in the Windermere district. Australian interests have opened the Isaac mine at Briscoe and the same people have re-opened the Nip-and-Tuck. From the latter a considerable tonnage of high-grade ore has been packed down for shipment. It is expected to return about \$150 per ton. The Paradise mine still is producing. It is the most consistent producer of the district.

ONTARIO

EMPLOYEE'S SICK BENEFIT FUND AT COBALT

COBALT.—Co-operation between the mining companies operating in the Cobalt silver area with the members of the Workmen's Central Council has resulted in a scheme to establish an Employees' Sick Benefit Fund. A charter has been applied for and the Fund will be placed in operation as quickly as possible. Workmen are to pay 75c. monthly, this amount being deducted from their pay. Companies are to pay an amount equal to the total contributed by the employees. The benefits consist of \$2.75 daily for not more than 13 weeks, with half that

amount for a second period of not more than 13 weeks. Upon death, the dependents shall be paid \$250. Complete returns of a vote of the workmen show a majority of 84% in favor of the scheme.

Operations are to be resumed within a few days on the Beaver Consolidated. Repairs to the mill are almost completed. The supply of hydro-electric power is still below normal, and the outlook is uncertain. Without rain or a general thaw before the arrival of winter, operations as a whole may not exceed half capacity throughout the winter in Cobalt. Rain and a few warm days would quickly release large volumes of water lying in the swamps and small streams. The zone of mineralization at the 385-ft. level of the Chambers-Ferland mine is broadening out as work proceeds. Officials declare the find to be one of the most important in the company's history. Work is still confined to the slate formation, but a winze is to be put down into the underlying conglomerate, which is believed to be the source of the silver mineralization found in the slate.

PORCUPINE.—Production at the Hollinger Consolidated is being speeded up. To relieve the situation caused by shortage of power several carloads of coal have been received, which will be used to operate the air-compressing plant. The staff is being steadily increased and a larger tonnage of ore treated, some days reaching as high as 1900 tons. The Dome Mines is also preparing to use its auxiliary steam-plant.

The McIntyre has done considerable drifting on the new vein recently found on the 1375-ft. level with encouraging results, the gold content maintaining a good average though unevenly distributed. One section, 60 ft. long, gives high assays, the vein being much leaner in other places. The vein will be known as No. 7. Drifting is also being done on No. 5 vein at the 1375-ft. level, and the 1500-ft. level is being opened showing gold content that confirms the results of diamond-drill exploration. The dividend of 5% declared by the McIntyre payable January 1 brings the total returns to shareholders up to \$2,166,169, being 60% on the capitalization.

The Schumacher is planning to resume operations in the early spring, providing the necessary funds by the sale of 100,000 treasury shares. Development has been carried to the depth of 700 ft. with considerable ore blocked out and the property is equipped with a 200-ton mill.

KIRKLAND LAKE.—The Lake Shore during October treated 1570 tons of ore with a production of \$47,077, an average of \$29.98 per ton. This is a new high record. Since the beginning of production in March 1918 the Lake Shore has maintained an average of about \$25 per ton for a total output to the end of October of \$1,098,808, which is the highest average recovery ever made by a steadily producing Canadian gold mine.

Development work on the property of the Thackery Gold Mines, which includes 250 acres in Lebel township, has been discontinued owing to labor shortage. The results so far have been of an encouraging character and more work is planned for the spring.

THE MINING SUMMARY

ARIZONA

Ajo.—The copper production of the New Cornelia Copper Co. will be kept below 2,500,000 lb. per month until conditions in the copper market improve. This is a reduction of approximately 25% and is accompanied by a corresponding reduction in the force. A find of rich sulphide ore in the bottom of a 36-ft. shaft immediately south-east of Ajo, and not far from the New Cornelia property, is reported. The property in question was at one time known as the Ajo-Cornelia. There are said to be several stringers of ore in

plant, are under consideration. On account of the recent decrease in the demand for copper all construction work will be deferred until a little later.

CALIFORNIA

Calaveras County.—At the Victor gravel mine, formerly called the Rainier, situated near Angels Camp, the work of unwatering is proceeding. The big tank-skips are kept running incessantly and the water in the shaft is lowering much faster than was first anticipated. It is the opinion of the management that it will take constant hoisting for at least

ELECTRIC HOISTS AT THE INSPIRATION MINE

the bottom of the shaft, specimens of which have assayed as high as 45% copper.

Globe.—Curtailment of forces is taking place here as in the other districts throughout Arizona. The Old Dominion company has found it necessary to lay off approximately 200 men, as well as a number of shift-bosses, while the three shifts still employed at the Inspiration Copper Co have been reduced by a total of approximately 100 men. No material reductions are reported in the forces at the mills and smelters.

Superior.—A general program of improvement and expansion is planned by the Magma Copper Co. It is reported on good authority that plans covering the widening of the narrow-gauge railroad line, and the erection of a smelting

three weeks more to free the mine of the accumulated water.

Development of new territory from the recently deepened shaft of the Morgan mine is proceeding with good results. In the new levels the veins are said to be showing the same high-grade quartz as in the upper workings, with all indications favoring persistence of the orebodies to greater depth. The Morgan is one of the premier gold yielders of California and is controlled by W. J. Loring of San Francisco.

Shasta County.—The Globe and Chloride-Bailey mines, near Dedrick, have been sold to J. N. Kilner of New York and Charles Farmer of Hayfork by the Bulkeley Wells interests. Wells retains ownership of the large cyanide plant and plans to dismantle and ship it to his properties near

Gold Hill, Nevada. The Globe is equipped with a large mill and for several years ranked among the foremost gold producers of Trinity county. New orebodies were recently uncovered in the lower tunnel and a considerable tonnage of profitable ore is reported in sight. The new owners plan to operate the two groups and will probably continue development throughout the winter months.

IDAHO

Coeur d'Alene.—The International Mining & Metal Corporation has put miners to work at the Inland property where 600 ft. of development work has been done. The lower working, a 300-ft. adit 250 ft. below the outcrop and an 11-ft. winze, exposed an 8-ft. vein of zinc-lead-silver ore. Assay of ore from the lowest workings gave 27% zinc, 24% lead, and 9 oz. silver. The high-grade lead-silver went 60% lead and 25 oz. in silver.—Men have been put to work on the Silverado mine, near Osborn. The company has a mill, including flotation, and expects to commence production soon. The vein has been drifted on, exposing a good orebody one to four feet wide.

The tunnel of the Pine Creek Mining & Milling Co. is in 250 ft. The tunnel is following the foot-wall, the vein in the face of the tunnel being eight feet wide. The quartzite is freely impregnated with galena and there is a small streak of lead-silver ore carrying little zinc.

Leona.—After years of preparation and construction water has been turned into the canal to supply the giants of the Idaho Gold & Ruby Co.'s placer enterprise. No mining enterprise in the north-west has elicited more favorable and unfavorable opinions than Idaho Gold & Ruby. Those who have confidence in the project, believe it will be the producer of millions.

NEVADA

Arrowhead.—The Arrowhead company has erected a 36-ft. steel head-frame and a 25-hp. gasoline-engine for continuing sinking of the shaft, which is now 325 ft. deep. It will be continued to 350 ft., or 183 ft. below the 167-ft. level, the deepest on which lateral work has been done. When 350 ft. is reached drifts will be driven at this depth.

Divide.—The hanging-wall drift on the 800-ft. level of the Tonopah Divide is in ore assaying \$100 and more for the width of the drift, according to an official statement. The drift on the 1000-ft. level is in low-grade ore.

Manhattan.—The west orebody of the 300-ft. level of the White Caps has been entered on the 500-ft. level. The ore is free-milling, as on the upper level, and the value is \$20 to \$25 per ton. This orebody is distinct from that in the eastern part of the mine, which has a heavy sulphur and arsenic content.

Virginia City.—The Gold Hill labor trouble has been settled as a result of conferences between Governor Boyle, Bulkeley Wells, president of the United Comstock, and the Gold Hill miners' union. Miners are to receive \$5.50 until May 31, 1921, and \$5 from then until November 30, 1921. Top-men will be paid \$5 and \$4.25 in the same periods, as will laborers in the mill, and after November 30, 1921, the wage for them is to be \$4. The Virginia City mine operators will pay this new Gold Hill scale when their present agreement with the miners ends on January 1, 1921.

Regis Chauvenet, president emeritus of the Colorado School of Mines, died at Denver on December 6, at the age of 78. Born in Philadelphia, he graduated from Washington University, St. Louis, and obtained a post-graduate degree at Harvard. He started his career as a chemist at St. Louis; in 1883 he became professor of chemistry and president of the Colorado School of Mines, retaining this appointment for nine years, during which time he contributed largely toward the growth and improvement of the School.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

R. K. Neill has returned to Spokane from New York. **Dwight E. Woodbridge**, of Duluth, is at Portland, Oregon. **Charles Butters** has returned from New York to Oakland. **Lloyd C. White** has returned from a month spent at Kellogg, Idaho.

Solon Spiro, president of the Silver King Con. M. Co. of Utah, is in New York.

George E. Hyde has been appointed vulcanologist to the Mexican Geological Survey.

Oscar Lachmund has returned to Spokane from China, after an absence of six months.

J. D. Shilling, general superintendent of the Utah Copper mine at Bingham, is in Florida.

Walter E. Gaby has been appointed geologist for the Santa Gertrudis company, at Pachuca, Mexico.

M. G. F. Sohnlein is visiting Western mining camps, on his way to Chile after an extended trip to Europe.

N. J. Martin, mining engineer associated with the New Idria Quicksilver Mining Co., was in Utah recently.

Stanley A. Easton, manager for the Bunker Hill & Sullivan company, has returned to Kellogg from Washington.

A. J. Taylor, of the Dolly Varden Mining Co., Vancouver, passed through San Francisco on his way to Los Angeles.

J. Parke Channing, vice-president of the Miami Copper Co., has been elected president of the Seneca Copper Co. of Michigan.

L. W. Kemp has been appointed general superintendent of the reduction works of the Chile Copper Co., at Chuquicamata.

Glenn D. Cook, general manager, and **F. M. Cook**, treasurer for the Pershing County Mines Co., are in San Francisco from Oreana, Nevada.

C. W. Botsford has been spending two weeks at Magdalena, New Mexico, making geological examination of properties owned by S. S. Lang.

J. L. Oldright, superintendent of the leaching division of the Chile Copper Co.'s plant at Chuquicamata, is visiting metallurgical plants in Utah.

Robeson T. White, for several years general manager for the Braden Copper Co. at Rancagua, Chile, is spending his vacation in southern California.

J. M. Callow, president of the General Engineering Co., spent the month of November at his New York office, and has now returned to Salt Lake City.

C. W. Whitley, vice-president of the A. S. & R. Co., is making a trip of inspection to the Western properties of the company. He is now at Salt Lake City.

Hiram W. Clark, consulting engineer for the U. S. Bureau of Mines at the University of Utah, has accepted the position of deputy smoke inspector of Salt Lake City.

Mototaro Ogino, vice-president of the Furukawa interests in Japan, sailed from San Francisco on December 3 for Yokohama. He spent four months in Europe, Canada, and the United States.

T. H. Jenks is at Denver, having completed the work he has been engaged upon in Colorado all summer. Before returning to Los Angeles he will examine properties in New Mexico and Arizona.

Huston Thompson, of Denver, became chairman of the Federal Trade Commission on December 1 for a term of one year. Mr. Thompson, who was vice-chairman during the past year, succeeds to the chairmanship under the rule of the Commission that provides for rotation in the office of chairman among the several commissioners.

THE METAL MARKET

METAL PRICES

San Francisco, December 7

Aluminum-dust, cents per pound	65
Antimony, cents per pound	7
Copper, electrolytic, cents per pound	14
Lead, pig, cents per pound	5.25-6.25
Platinum, pure, per ounce	\$85
Platinum, 10% iridium, per ounce	\$125
Quicksilver, per flask of 75 lb.	\$55
Spelter, cents per pound	8
Zinc-dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

December 6.—Copper is quiet and steadier. Lead is inactive and lower. Zinc is quiet and stronger.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

REPEAL OF EXCESS-PROFITS TAX

Speaking before the Economic Club, Jules S. Bache declared the excess-profits tax must be repealed and an adequate, practical, and honest tax enacted in its place. The latter tax is the gross-sales, or turnover tax, he says. The other substitute favored by many is the retail-sales tax, which Mr. Bache opposes because of the element of personal judgment that will come into play as to what a retail sale is and probability of a 3% rate in order that the tax may yield as much as a 1% gross-sales tax.

Mr. Bache expressed belief that the Republican Secretary of the Treasury will "promptly take such measures as will restore prices of Government obligations to prices paid by patriotic citizens."

"It would be a most simple financial scheme that would restore these bonds to vicinity of par, and permit of funding Victory bonds when due, at that price, and, with that done, the largest budget, including service of the debt, that we need contemplate, would be under 3 1/2 billions, instead of the large amount fixed by the Secretary of the Treasury in his report."

"Freeing of capitalists from excessive burdens of taxation," according to Mr. Bache, "would take the advantages out of the municipal-bond investments, and release capital for constructive enterprises to an extent almost incalculable."

"We would not have witnessed the recent debacle in securities markets if large investors were still functioning in our money market. I believe the absurdly low prices of investment securities recently are due almost entirely to surtaxes on income."

He summarized advantages of the sales tax in this way: "It is simple where the present system is distressingly complicated; it will produce ample revenue, whereas taxes now imposed, as profits and incomes decline, must fall far below amounts required; under the sales tax, Government revenue is based on something tangible, namely, expenditures of the people which go on unceasingly and do not vary in hard times or good times to such an extent as seriously to affect revenue; it will stop capital from hiding in tax-exempt securities; it allows the country to save funds for future industrial expansion; it will reduce competition, enterprise, and individual initiative, now smothered to death by pursuit of the tax gatherer; it will encourage business thrift, stopping waste of high salaries and extravagances, which can no longer be charged off against taxes; its collection is simple and automatic for both Government and tax-payer; it is fair in distribution, as the one who consumes most and spends most, pays most in taxes."

"It will not increase the price of commodities beyond an average of 2 1/2%, whereas now taxes increase prices quarterly 25%; consequently, it will tend to reduce present prices to marked degree; it has been in successful operation in the Philippines for years and has proved in every way satisfactory; it has recently been put into operation in France and is thus far strikingly successful; some forms of it are in operation in Canada, and it is so satisfactory that leading interests there are urging that it be adopted as a complete substitute for all other taxes."

"It is based on sound democratic principles, and by reaching out into new sources of revenue spreads the tax load equitably and in a way most easily borne by all; as it will be passed along to the consumer, millions will pay the tax, but nobody will know or feel it; it enables every taxpayer to know his tax liability."

MONEY AND EXCHANGE

Foreign quotations on December 7 are as follows:

Sterling, dollars:	Cable	3.43 3/4
	Demand	3.44 3/4
France, cents:	Cable	5.89 1/2
	Demand	5.85 1/2
Lire, cents:	Demand	3.5 1/2
Marks, cents:		1.30

Eastern Metal Market

New York, December 1.

The downward tendency continues in all the markets without exception; prices have touched new low levels in all metals on this movement. This is also true in London which has a marked effect here.

Copper has sold in moderate quantities down to 14c. and the market is weak.

Tin has touched still lower levels and there is little animation in the market.

Lead has continued to decline on offerings with no buyers. Demand for zinc is very small and forced offerings by weak interests have sent down the price.

Antimony is again lower.

IRON AND STEEL

The outstanding feature of the week's developments has been the announcement of a recession to the Steel Corporation's prices on bars, shapes, and plates by two leading independents, followed by practically all of the rest. This also is understood to apply as well to sheets and wire by most of the independents. Just how this will affect companies having fair orders on their books is problematical and is to be decided in individual cases. The net result means keener competition for such new business as develops, both domestic and foreign. The only major product which may be said to remain firm is pipe in which there continues a marked divergence between independent and corporation prices. Nails are down a dollar per keg at Pittsburgh.

The pig-iron market is stagnant and more furnaces are closing down. There is a tendency to limit the piling of stocks and production is falling to around 50% of capacity. It is really a buyer's market.

COPPER

Of paramount interest is the fact that the United States Steel Corporation yesterday, Tuesday, bought 500 tons of electrolytic copper at 13.50c. Further details are lacking. This purchase, taken together with the reported sale last week of 500 tons at 14c., by the American Metal Co. would seem to indicate that the decline in the copper market, which has been in process for some weeks, was somewhere close to the bottom. Offerings by small producers or dealers on a small scale have progressed daily and been a cause of continued weakness. Several of the large producers are not quoting but are willing to consider desirable business at 14c., New York. The London market is also much lower, spot standard yesterday having been quoted at 275 5s. and futures at 275 15s. On November 18 the former was 283 per ton. Buying except in the cases noted is light and confined to small lots by small producers and dealers. Lake copper is nominal at 14c., New York. We quote electrolytic at 13.50c., New York, for December and first quarter.

TIN

The market is dull and without much activity so far as buying is concerned. Prices continue to decline but the unsatisfactory New York market commences to show signs of correction from the fact that large dealers and importers are refusing to sacrifice metal or to sell at less than cost of import. This tendency, if persisted in, is expected to make for a better market. There have as a consequence been only a few sellers all the week unless they could secure import cost at least. There have been some buyers of cheap tin but not much of this has been available. As a result there have been few sellers and not many buyers. The feature has been the low prices in London—lower than in many years. Yesterday spot standard fell to £207 10s., future standard to £212, and spot Straits to £208 per ton. Last week these quotations were respectively £230 15s., £234 15s., and £231

5s. At one time this year spot Straits sold at over £400 per ton. The quotation for spot Straits yesterday was 33.50c., New York, the same as on Monday. Arrivals thus far this month have been 3170 tons with the quantity afloat 3180 tons.

LEAD

New low levels have appeared in this market in common with all others. London prices have been an influence here too. Yesterday spot lead was quoted at £25 with futures at £26 per ton. The former means an import price here of around 5.40c., New York, duty paid. On November 18 this price was £32 per ton in London. The outside market here has fallen to 5.25c., New York, and St. Louis, at which offerings have been made. The leading interest has not yet changed its quotation of 6c., New York and St. Louis, but is expected to lower it any day. In general it may be said that most independent producers are offering lead liberally, but whether this is done because of a desire for orders or in order to realize as high prices as possible during the decline is a matter of argument. One opinion is that neither supposition is right but that the London decline is the main factor.

ZINC

Offerings continue to be made at concessions for the little business going and prices show no tendency to 'firm up'. New low levels have been realized in the week. Prime Western for early delivery has been offered and sold at 5.60c., St. Louis, or about 6c., New York, but the tonnages involved are small. Cash necessities have been the deciding influence in most cases and have been participated in by small interests. Large producers are meeting present prices only when necessary and in limited tonnages and all are curtailing output. It is estimated that the present rate of production of prime Western is about 275,000 tons per month, and that it will decline to about 225,000 tons for the December rate. London has declined decidedly, recently. Yesterday spot zinc was quoted at £29 7s. 6d. with future shipment at £35 2s. 6d. On November 18 the former was £35 2s. 6d.

ANTIMONY

This market is slightly lower. Wholesale lots for early delivery are now quoted at 5.75c., New York, duty paid, with demand light. Jobbing lots are about 3c. higher.

ALUMINUM

Virgin metal, 98 to 99% pure, is lower in the outside market at 25 to 26c. per pound, for wholesale lots for early delivery. The leading interest's quotation is unchanged at 32.90c., f.o.b. producer's plant.

ORES

Tungsten: The absence of demand continues sharply to characterize the market. Buyers will not consider any offerings. Quotations continue nominal at \$4 per unit for Chinese ore and at \$5 per unit for Bolivian.

Ferro-tungsten is being offered by Washington, D. C., producers at 59c. per pound of contained tungsten, but the market is quiet.

Molybdenum: The nominal quotation of 60c. per pound of MoS₂ in regular concentrate continues.

Manganese: The market is devoid of demand and quotations are nominal at 45 to 50c. per unit, seaboard, with some sellers asking 50 to 55c. for future positions. Stocks are believed to be heavy.

Manganese-Iron Alloys: There is no interest from consumers and quotations are largely nominal at \$150, delivered, for domestic ferro-manganese and \$72.50 for 20% spiegeleisen.

HEAT

that can't be measured

THANKS to Oxweld—the tremendous energy of the Oxy-acetylene flame—limitless, to all intents and purposes—is ready to work *your* will at a twist of the fingers.

The oxwelder's torch has shortened production time in many hundreds of plants; and as a saver of time, labor and expense in factory repairs it pays for itself many times over annually.

In fostering and developing the oxy-acetylene process from its inception, Oxweld has taken a big part in the Nation's manufacturing development, for there is scarcely a branch of industry to which oxwelding and cutting is not applied to great advantage.

There are Oxweld Service Engineers in more than fifty important cities, ready to investigate the Oxweld possibilities of your plant.

Write, wire or telephone to any of the addresses below for immediate attention.

OXWELD ACETYLENE COMPANY

WORLD'S LARGEST MAKER OF EQUIPMENT FOR
OXWELDING AND CUTTING METALS

NEWARK, N. J.

CHICAGO

SAN FRANCISCO

T. A. RICKARD, Editor

ONLY \$2,500,000 out of the \$8,000,000 appropriated by Congress for the relief of claimants under the War Minerals Relief Act has been awarded by the commission appointed for that purpose. Either the legitimate claims were few or the Commission has failed to perform its proper function.

ASSESSMENT WORK on mining claims is likely to be affected favorably by Congressional legislation now pending. The bill extending the time for such annual work has been reported favorably by the mines committees of both the Senate and House. The Senate bill asks six months relief, the House bill twelve months. Some measure of relief seems assured.

IN our issue of December 4, under 'The Flotation Conference', we quoted the telegram from Mr. Ballot concerning Minerals Separation claims to royalty. The text of the telegram we took from a report of the proceedings, but it was not quite correct. We are informed now that it should have read as follows: "The answer to your question is No, we do not claim payment of royalty for use of first patent in suit or any other patent after its legal expiration. But we do claim payment of royalty for the use of any other of our unexpired patents."

PRODUCTION of gold on the Rand for the current year will be about 250,000 ounces less than in 1919, but the money received for it will be nearly \$40,000,000 more, owing to the so-called premium on gold. Up to the end of October the normal value of the output, at 85 shillings per ounce, was £29,272,604, whereas the declared value was £37,281,979. Scarcity of labor has restricted production during the last quarter of the year, the decrease in the supply of Kaffirs being in excess of the customary seasonal variation. In April the total of native laborers on the gold mines was 189,446; at the end of October it was only 159,426.

SPEAKING of Mr. Vanderlip's Russian schemes—not Mr. Frank A. Vanderlip of New York but Mr. Washington D. of California—the 'New York Times' says that he may believe what he says, "but he comes from Los Angeles, a city where long contemplation of the climate has developed the lens of the human eye into a high-power magnifying instrument, and close association with

motion-picture press-agents has induced a carelessness in arithmetic". That is 'one on Los Angeles', but we take the opportunity to express admiration for the enterprise of the people in the southern metropolis and congratulate them, among other things, on their freedom from the tyranny of the labor-unions, which has crippled the growth of San Francisco.

A SUM of \$170,000 has been asked by the U. S. Bureau of Mines for investigation of the possibilities of obtaining oil from shale. An official bulletin says that "notwithstanding the considerable amount of moneys which have been expended up to the present time, there is not an oil-shale plant producing oil in commercial quantities in the United States". What is needed, we are told, is "essential and fundamental information"; as if Dr. Alderson and his friends had been giving some other kinds of information! We venture to suggest that the Standard Oil Company, and other oil companies, could furnish all the data needed on the subject for the purpose of correcting the misinformation circulated by enthusiasts and wild-cat promoters; but probably they prefer to keep their information in cold storage.

PRODUCERS of silver at Cobalt, who last January were getting \$1.37 per ounce for their bullion in New York, wonder if they will wake up and find that the present 60-cent market is only a melancholy dream. There is still a good profit for most of the companies, but a drop to 46½ cents, the quotation on September 1, 1915, would leave only one or two survivors. Nipissing produced silver during 1919 for 37 cents per ounce, while the Coniagas, Kerr Lake, and O'Brien companies all held their cost below 50 cents. A number of others, however, were unable to do better than 65 cents, and since it is generally conceded that costs have increased slightly since 1919 it is easy to account for the recent passing of dividends and the suspension of operations at some of the properties. The scale of wages paid is the highest in the history of mining in Ontario and there has been little recession in the price of supplies. Economy and efficiency will succeed the effort for high production at any cost that prevailed a year ago. Miners and other employees realize that the only way to maintain their present wages is to do enough work each shift to keep the cost per ounce within a fixed limit. The output per man is said to have been increased 30% without any urging on the part

of managers and superintendents, thereby demonstrating the efficiency that results from voluntary concerted effort. The fact that some of the other companies have released their men has had an important influence on improved production at the mines that continue to operate. Incidentally, the Nipissing company produced 260,865 ounces of bullion during the first week of December.

LAST week our community went through an orgy of crime and newspaper sensationalism, the latter being not unrelated to the former. Three men were arrested for mistreating two young women; when arrested, they shot and killed three members of the police; a few days later they were lynched by a mob. Photographs galore have been published of the criminals, of the girls themselves, whom one would expect to seek retirement, and of the lynching. During the period of these happenings the front pages, and others besides, of our local papers have been devoted to this hideous affair, and the atmosphere of a cheap cinema has prevailed. The Chief of Police threatened to arrest every idler, thereby menacing many politicians. The Mayor ordered the remains of the murdered policemen to lie in state in the City Hall. The one dignified note was that sounded by the Governor in a statement gravely reprobating the lynching. Of course, to try to cure crime by breaking the law is bad citizenship. It cannot be done in that way; it merely disgraces our commonwealth by acknowledging to the world that justice is not promptly or certainly enforceable among us. Much of the crime in our city, as in others, is due to the low character of our police judges, who are elected, and who, by being corruptible, hinder the efforts of the police to bring criminals to account. It is due in part also to the low character of such of the policemen as indulge habitually in graft, that is, the collection of tribute from the vicious element in our city population. A correction of this state of affairs must come through the awakening of public opinion and the introduction of reform in the departments affected, but this cannot be done so long as we are dominated by an irresponsible and meretricious press. The perpetration of crime is stimulated by the notoriety given to criminal acts; moreover, a morbid love of publicity will incite some perverted young men and women to the breaking of the law. The yellow newspaper is assisted by the depiction of criminal acts by the cinema. We note with satisfaction that the legislature of Pennsylvania has passed a law forbidding the exhibition of 'movies' devoted to crimes of violence. It were well if the newspapers could be restrained similarly.

WHEN a carload of ore is sold it becomes necessary, in order to fix the price, to know how much gold, silver, lead, copper, zinc, or other metal it contains. If it were practicable to treat the particular lot separately and reduce and refine the metal content to bullion without mixing with other ores or other products, settlement might be delayed until the process was completed. There are obvious and insurmountable objections to such a procedure even aside from the difficulty that would be ex-

perienced in selecting a suitable metallurgical treatment unless the composition of the ore were known definitely. Moreover, the grasping smelter manager would be unable to adjust his penalties with his accustomed cunning. To overcome these difficulties our metallurgical predecessors devised two processes, namely, sampling and analysis. The object of sampling is to obtain a small portion, say, a gramme or an assay-ton, the composition of which, for practical purposes, is identical with that of the entire lot it represents. The object of such analysis is to determine quickly and conveniently how much of a metal or other element resides in the small sample. A simple calculation then determines the quantity of that particular element in the original carload of ore. Sampling and analysis are interdependent; either is useless without the other, and a degree of precision in either in excess of that attained in the other is worthless. It is impossible to weigh, to titrate, and to perform other laboratory manipulation with absolute accuracy, so that there is an allowable limit of error in all such determinations, the degree depending upon the element being determined and the amount of it that is present. The aim, then, is to obtain a sample that is not less accurate, at least, than the subsequent chemical analysis will be. An important consideration in determining the degree of refinement of sampling is the practical factor of cost. Here common sense is the guide. In this issue Mr. H. B. Pulsifer, formerly of the Montana State School of Mines at Butte, and now Professor of Metallurgy in Lehigh University, at South Bethlehem, Pennsylvania, contributes a valuable article on 'Sampling Methods in Montana'. The first part of this article, which deals with the general principles of sampling and suggests directions of possible improvement, will be followed next week by a second, dealing in detail with the methods used at Butte, Anaconda, and East Helena. Professor Pulsifer was given every opportunity to test the different plants, and the results of his work and his observations are carefully recorded. We believe that every seller or purchaser of ore, as well as every operator of a mill or smelter, will find the article well worth careful reading.

NEWs comes to us that Mr. Gelasio Caetani has been elected Mayor of the City of Rome. His many friends in the profession will be keenly interested to hear about this and will join us in cordial congratulations. As on many other good engineers the War had the effect on him of engaging his interest in civic affairs, with a determination to do his part in the work of reconstruction that faced each of the countries lately belligerent. Our readers know that Mr. Caetani played his part finely as a soldier, rising to the rank of Colonel in the Italian army and making himself famous by the affair of the Col di Lana, in which as an officer of engineers he undermined and destroyed a strong Austrian position, killing or capturing all its defenders. In these days when all sorts of miserable tales and sordid relationships are dubbed 'romantic', it is pleasant to recall Mr. Caetani's career as a mining engineer in our West. He graduated

from the Columbia School of Mines when he had barely learned to speak our language, about sixteen years ago. After graduation he worked as a miner, trammer, timberman, and mill-hand at the Stratton's Independence mine in Colorado, at the Treadwell in Alaska, and at the Bunker Hill in Idaho, thereby learning the rudiments of his profession in a thorough manner. He asked no favors but 'went through the mill' with a keen determination to prove himself a capable technician and render himself fit for positions of responsibility. Only his personal friends knew that he was Don Gelasio Caetani, the son of the Duke of Sermoneta and a scion of a historic Italian house of great wealth and influence ever since A.D. 981. By his antecedents, as by his personal charm, he reminds us of Anthony Hope's Prince of Ruritania, and also of one of Marion Crawford's most attractive characters. Indeed, in 'Saracinesca' several members of the Caetani family are supposed to be portrayed. Be that as it may, our mining engineer is no fiction, but a virile personality, who promised to be one of the leaders of the American mining profession until the War and its after-effects diverted his energies to new activities in his own country. Mr. Caetani, to give him his American title, designed the newest of the big mills of the Bunker Hill & Sullivan company; he won recognition on his own merits as a metallurgist, and demonstrated that a pedigree is no bar to a capacity for doing hard work among hard workers. We feel sure that the qualities of mind and person that distinguished him when among us will aid him in achieving success in the splendid task of directing the municipal administration of the Eternal City.

Impressions of the Mining Congress

In a recent issue we gave an account of the flotation conference, which was one of the features of the recent convention of the American Mining Congress. Other phases of the meeting are worthy of reminiscent remark. The sessions unfortunately were held in a Baptist church and at first, particularly at the opening ceremonies, the ecclesiastical environment exercised an unduly sobering effect, checking applause and chilling humor, but the gentlemen of the convention soon threw off this unwonted restraint and enlivened the proceedings in a normal manner. The discussion on the deplorable state of gold mining assumed a pessimistic character, thereby evoking support of the McFadden bill. Mr. H. N. Lawrie, economist to the Congress, read an excellent resumé of the argument therefor, and sundry mining engineers portrayed the adverse conditions under which gold mining is being conducted today, in order to prove the need for relief, but when a paper was read on 'Oregon and the Gold Problem' it became evident that a sense of economic perspective is needed in this matter as in others that have world-wide implications. Oregon produced \$1,071,000 worth of gold in 1919. Mr. E. P. Mathewson took the chair, after having confessed that he had been converted since last year, the change of conviction in favor of the McFadden bill having been brought about by his

observation of the effectiveness of the Pittman Act. As to that favorable legislation, the less said the better just now. Governor Boyle of Nevada, the chief protagonist for the Western movement in favor of a bounty on new gold, did not seem as confident as of yore, for instance, last March at Seattle. He appeared to show the effects of his recent contact with bankers and economists at Washington, and, we venture to suggest, has begun to appreciate the misgiving with which thoughtful men view anything in the nature of a double standard. However, the McFadden bill was duly endorsed, although another resolution advocating the increased circulation of gold by means of a bank to be run in behalf of the gold miners was shelved. The 'open shop' has received vigorous support from the Mining Congress and it formed the subject of a special session, at which Mr. Arthur Notman described the conditions of labor employment at Bisbee and Mr. Charles A. Chase the operation of the open shop in Colorado, these two papers being followed by an excellent speech on labor conditions in Denver by Mr. L. Ward Bannister, who insisted that the unions must be made amenable to judicial process. Such discussions are interesting, but one cannot but feel their unreality in the absence of any representative of labor; how much more useful they would be if they took the form of a friendly debate! Too many statements pass unchallenged when only one phase of a controversial problem is presented. There were other conferences on the tariff, standardization, taxation, and education, but we were not present at these. As usual, several persons on the program failed to appear, it being a common practice on the part of the promoters of these conventions to announce addresses from prominent individuals for the sake, naturally, of exciting public attention; nevertheless the attendance was large and representative, the various Government bureaus sending officials competent to speak for them. Among these were many men well known and much liked by the mining fraternity. Several mining schools were represented at the conference on education. The editors of the two leading mining papers attended, and took part in the discussions.

The annual meeting was sparsely attended, for, truth to tell, these conventions attract many who are not members, and, after all, the total membership of the Mining Congress is small, only 2500. The Secretary, Mr. J. F. Callbreath, read his annual report; indeed he is the man behind the gun; an institution is usually the lengthened shadow of some one man, and to Mr. Callbreath's initiative, persistence, and singleness of purpose the Mining Congress owes its continued existence and its present character. He deprecates the use of the word 'lobby', but, as we have said before, using that word in no sinister sense, the Mining Congress is a valuable lobby established at Washington in the interest of those engaged in the mining industry. That is one function it performs; another is to serve by its conventions as a parliament of mining men, affording an opportunity for the ventilation of current ideas and the discussion of fundamental problems. It ought to have a larger mem-

bership, for if it is to be supported financially not by its members but by the doles of a relatively few large mining companies it will become the spokesman of only a small part of the industry. That is its danger, as we see it. Personally we find its meetings interesting because the politics of mining and the humanistic phases of the industry are more absorbing mentally than the technology of the mine and mill. There is need for such conventions and we hope that the Mining Congress will develop its activities to ever-increasing usefulness. The usual banquet marked the close of the meeting. Mr. Thomas B. Stearns, a mining engineer by education and a citizen whom the people of Denver evidently hold in the highest regard, was an agreeable and efficient toastmaster. The outgoing president, Mr. Bulkeley Wells, received an ovation; the incoming president, Mr. W. J. Loring, was accepted with enthusiasm. The chief speech of the banquet was delivered by Senator Charles S. Thomas, whose sardonic humor was brought to bear upon the 18th Amendment, and the disregard of it; for this evidence was not lacking, much to the satisfaction apparently of many of those present, who probably would agree with us that the air of Colorado is dry, but stimulating. In any event, Denver is a first-rate place for a convention, for is not the climate invigorating, are not the people hospitable, and is not the golf-course a good test of the game? We seem to hear many voices in support of the motion; it is so ordered.

The Impending Labor Crisis

Notice has been given of a reduction of \$1 per shift in wages paid at the copper mines of Arizona, this reduction to go into effect on January 1. Similar steps have been taken in other mining districts. It was inevitable. Wages were advanced when the price of copper was high and the cost of living was advancing by leaps and bounds; wages must come down when the price of copper is low and the prices of staple commodities are tumbling. The question is whether this unpleasant readjustment and others of the same character will be made fairly and in an orderly manner. The 'New Republic' anticipates a concerted attack on labor-unionism under cover of a crusade for the 'open shop'. Union labor undoubtedly is on the defensive, as a short time ago it was on the aggressive. Unfortunately organized labor is grasping and greedy when it gets the chance, and unfortunately organized capital is equally so when it gets the chance. The fair-minded and conservative elements on both sides are in a minority. The 'New Republic' says that the trade-union is "capable of control by popular referendum of its personnel". It might be capable of it if all the members voted, but, as a matter of fact, the unions, like the groups of corporations, are led and controlled by a small number of extremists. What the mass of workers want is not the 'closed shop', but steady employment at a reasonable wage. The uncertainty of employment is the curse of the workingman, and that uncertainty no union can correct; but it may be corrected

by systematic co-operation between the corporations and the unions looking toward the benefit of industry, and of the community, as a whole. Just now the public outside the laboring class will view any recession in wages as inevitable and even desirable, for without it the readjustment to the after-the-War conditions cannot be completed. Moreover, there is a feeling that the laboring class has used the War and the 'high cost of living' as a lever for excessive demands in wages. All of us have been the victims of extortionate charges, made by all sorts of workers, from carpenters to cooks. There has been 'profiteering' at both ends, by the manufacturer and by his workmen, while the rest of us, the public at large, has had to pay extortionate tribute to both. The War and the conditions it created were accountable for only a part of the rise in commodity and labor prices; at least half was factitious and fundamentally dishonest. Mr. Samuel Gompers and his Labor bureau at Washington are said to have made "a sweeping investigation of living costs throughout the United States" and they are now ready to present Congress with "a complete program of anti-profiteering proposals", aimed against "the big corporations". The pot calls the kettle black. The heroes of our back line of defence collected \$8, \$10, and \$12 per diem for three or four hours work, or less, in our dockyards and factories during the days of national stress; they 'profiteered' to the limit, and beyond; the men in the building trades extorted all kinds of fanciful wages; in California domestic servants more than doubled their scale of pay, although the fact of their being given board and lodging protected them from the impact of the high cost of living. Now Mr. Gompers and his friends plan to stop immigration in order that "the reactionary element" may not "re-establish autocracy in industry". They would like to so curtail the supply of labor as to place the employer class at their mercy, and thereby establish their own "autocracy". Well, it is not unnatural that they should seek to protect themselves, even at the expense of the country as a whole, for, whether it be a leader of labor or of capital, it is yet too early to expect from either any reasonable unselfishness, or even social justice. Judge Gary will offset Mr. Gompers. Meanwhile we have a government of the people and for the people, by the representatives of the people. It seems as if our Department of Labor, if it were competent, that is, just and thoroughly informed, could shed light on some of these difficulties, and perhaps even help to straighten them out. Or must we go through another series of lock-outs, strikes, and general turmoil to reach another temporary armistice between capital and labor? What is needed—and we say it again and again—is the enlightenment of the public, not by specious propaganda from both sides, but by an unprejudiced statement of the case, after competent and impartial investigation, so that the full force of the good sense and justice of the nation may be arrayed against the greed of either side and in behalf of an economic peace that shall do justice to all concerned, including that *tertium quid*, the mass of the people outside the vendetta.

DISCUSSION

The Divining Rod

The Editor:

Sir—Apropos of your editorial on this subject in a recent issue, I am impelled to contribute a reference testifying to the prevailing practice and wide use of the witch-hazel or divining rod in the 'forties and for many years previous. This reference I find in the introductory pages of a school-book on geology published more than half a century ago. Its quaintness of language recommends it to the notice of your readers.

It is recorded that this book was entered according to Act of Congress in the year 1845, Eastern District of Pennsylvania, and published under the title 'Elements of Geology', J. B. Lippincott & Co., Philadelphia, 1856. The author, W. S. W. Ruschenberger, M.D., attached to the U. S. Naval Hospital, New York, in his preface writes:

"A competent knowledge of Geology better enables the architect to select materials for buildings, as well as sites for their erection; the engineer learns from it where he may run a railroad or canal with the greatest facility, and least cost; the miner is guided in the pursuit of mineral wealth, metals or coal, with greater certainty of success when assisted by this noble science, which is more unerring than witch-hazel or divining rod; it facilitates the physician in the study of climate, and opens up a wide field to the divine for pointing out the wonders of creation and the goodness of God."

Denver, November 23.

FORBES RICKARD.

The Editor:

Sir—I was somewhat disappointed at your manner of handling the question of divining rods and water-witching in your last issue. Probably, because I am as intolerant of a superstition as a bull of a red flag. There is such widespread belief in this particular ancient hocus-pocus, and so many credulous persons are yearly gulled by means of it, that I think the subject merited more serious and critical treatment at your hands. You may be chagrined hereafter to see parts of your editorial quoted in the prospectuses of charlatans in support of their claims.

The article by William Pryce is interesting to antiquarians, but if you had reprinted Rossiter W. Raymond's historical review of the subject, published in 'Mineral Resources' for 1882, and in Vol. II of the Transactions of the American Institute of Mining Engineers, you would have contributed far more to our knowledge, and

at the same time, would have dealt some smashing blows at a childish and costly superstition. Raymond says in conclusion:

"To this, then, the rod of Moses, of Jacob, of Mercury, of Circe, of Valentin, of Beausoleil, of Vallemont, of Aymar, of Bleton, of Pennet, of Campetti—even of Mr. Latimer—has come at last. In itself it is nothing. Its claim to virtues derived from Deity, from Satan, from affinities and sympathies, from corpuscular effluvia, from electrical currents, from passive perturbatory qualities of organo-electric force are hopelessly collapsed and discarded. A whole library of learned rubbish about it which remains to us furnishes jargon for charlatans, marvelous tales for fools, and amusement for antiquarians; otherwise it is only fit to constitute part of Mr. Caxton's 'History of human error'. And the sphere of divining rod has shrunk with its authority. In one department after another it has been found useless. Even in the one application left to it with any show of reason it is nothing unless held in skillful hands, and whoever has the skill may dispense with the rod. It belongs, with 'the magic pendulum' and 'planchette', among the toys of children. Or, if it be worthy the attention of scientific students, it is the students of psychology and biology, not of geology and hydrosceopy and the science of ore deposits, who can profitably consider it."

The U. S. Geological Survey, in 1917, published a pamphlet entitled 'The Divining Rod', reviewing its history, and concluding, "It is difficult to see how for practical purposes the entire matter could be more thoroughly discredited."

GRANT H. SMITH.

San Francisco, November 20.

The Editor:

Sir—Several years ago a cattle-man living near Mariposa, California, at an elevation of about 600 ft., was puzzled as to how he could find water. He made the fact known to those in his employ. One of the men said, "I can locate water for you and will be glad to do so." The cattle-man said to him, "This is your opportunity to make \$50, providing you find sufficient water for domestic purposes." The man proceeded to look for water at once after cutting a forked branch from a sapling oak. Passing a certain point near the house the divining rod bent downward, crossing this point the rod rose to a vertical position, and then bent downward again over the man's back. Being satisfied that he had located the right spot, he took a straight branch about 2 ft. long and holding it over the spot he had marked, the branch bent up

and down 26 times indicating the depth at which water should be found. The well was dug; at a depth of 32 ft., a flow of water came into the well, rising to a depth of 5 ft. The water was fine and there was an abundance of it.

The gentleman who called at your office to ascertain where he could buy a divining rod to use in finding some gold buried near Vallejo probably is under the impression that the gold Winters stole from the Selby smelter several years ago was not entirely recovered and still lies buried near Vallejo. If this is his opinion, I can assure him that every ounce of gold bullion and four bars of refined gold were entirely recovered. I was assistant to the head refiner at the time of the robbery.

Two days after the robbery three divining-rod men appeared upon the scene at Selby and operated with their rods for several days between the Selby plant and Vallejo Junction. They stood upon the bank within 30 ft. of where Winters threw the gold into the bay. Although there was \$25,000 reward offered by the Selby company for the recovery of the gold, not one of these divining-rod men was fortunate enough to lay claim to any of the reward. There was \$283,000 in gold bullion and refined gold lying within 30 ft. of them under about 15 ft. of water. They disappeared as mysteriously as they appeared. The gold was not recovered until Winters confessed to the authorities and pointed out to them the exact spot where he threw the gold into the bay. Three detectives (who accompanied Winters, along with others) immediately stripped and recovered most of the gold by diving, in three hours. Three days later the detectives had recovered all the gold except the four bars of refined gold and a small bar of gold bullion weighing 18 oz. These were recovered by a professional diver.

W. A. MIDDLETON.

Martinez, California, November 21.

An International Association of Silver Producers

The Editor:

Sir—The severe fluctuation in the price of silver, in the open market, during the last year, is the very strongest argument to the governments of the world that silver is no longer a suitable metal to be used as money. Some of these governments will not look favorably upon the loss in value of their reserves, due to an abnormal drop in the price of silver. Others will lose confidence if they have to be repeatedly switching currency laws to follow an unstable market. Those individuals accustomed to hoard it will also lose confidence in its pre-eminence as an article of permanent value. In fewer words, a fluctuating price for silver means a continued reduction of demand, and consequently a serious and permanent factor in the reduction of average silver prices.

The great bulk of silver mining is done by fairly large companies who put their product on the market with little regard to the prices obtained. As far as possible, they work their mines at an even grade and tonnage of

ore, the principal exceptions being those mining silver as an auxiliary to copper. The policy of steady production may be logical from the point of view of economy in mining and treatment, but it fails to take into account the peculiar position of silver among the metals.

All silver passes through a refinery, but the refiner simply acts as middleman and has little concern about the market. When fluctuations become violent he protects himself by liquidating with the producer on the basis of the price at the date of sale of refined product. The buyers of silver are mainly the governments, for the middlemen do not speculate to any extent, and it is desirable that speculators should stay out of the market.

The burden of the proper regulation of market prices therefore rests between the governments and the producers. The governments can hardly be expected to buy steadily, because the demand is not steady; for example, it fluctuates with the conditions of crops and trade in the Oriental countries. Steady buying on the part of the governments of these countries would entail the storage of large amounts of silver over a considerable time, and such investment would draw no interest.

The producers, acting in concert, would be in a much better position to regulate prices, because they would be able to leave silver stored in the ground. In doing so, their investment in plant would not necessarily be lying idle, because with a reasonable market price for their product they could be mining and milling low-grade ores, and their expenses could be correspondingly cut, by a reduction of development and improvement.

If such an association as is here advocated were firmly established, and so properly and reputably maintained as to gain the confidence of the governments concerned, these would no doubt be willing to enter into contracts for the delivery of silver over a term of months at an agreed price, participation being distributed among the members of the association willing and able to comply with the terms of the contract. This would secure for the producers a security of market over that period, so that improvement in the mine and plant could be undertaken with entire assurance.

BLAMEY STEVENS.

Triunfo, Lower California, Mexico, November 20.

Mr. Hoover's Biography

The Editor:

Sir—Perhaps it may be permitted to other actors in the field to enter this amiable little discussion regarding Mr. Hoover and early days on the goldfields of Western Australia.

My own entry into Coolgardie was in January 1895, in the employ of Bewick, Moreing & Co., and I well remember (owing to the ravages of enteric fever) being the sole representative of Bewick, Moreing & Co., and of Alexander Mathieson, an allied mercantile company, and having our office in a contractor's hut in the middle of Bayley street.

The first permanent office was at the Coolgardie Chambers, 1895, and afterward extensive private offices of our

own in 1896. From 1894 to 1898—when I left—Coolgardie was the central office of Bewick, Moreing & Co. in Western Australia. As Mr. Wilson states, outside Hannan's Brownhill mine, the firm had no office at Kalgoorlie.

Now, as to single-jacking. At Kalgoorlie I was familiar with every hole in the ground, and the practice at every mine, yet I never remember seeing anything but double-hand drilling. On the other hand, I remember when Mr. Hoover came to Kalgoorlie, in 1897, showing him around the mines there, and when he went almost immediately to Lawlers, hearing of his introduction of single-hand drilling, from which a considerable economy was claimed. The 'Barrier', or Broken Hill, supplied almost all the men who became the operators on the Gold-fields, and practice there followed the 'Barrier'. Now, if single-jacking was prevalent at the 'Barrier', then it would doubtless have been followed in Western Australia.

Be that as it may, never in my experience did I see, at Menzies, Coolgardie, or Kalgoorlie, anything but double-hand drilling.

Now, as to Cornishmen teaching the world single-jacking. I have worked underground in Cornwall at Dolcoath, and spent my early days amid the mines there, but I never remember seeing an instance of single-hand drilling. The miners always worked in pairs. The hard tin 'capel' of the district necessitated a heavy 'mallet', with one man 'beating the boyer', and the other 'turning'. In my student days underground in Cornwall, I should much have appreciated the gentle art of single-jacking, and so have escaped the penalized inaccuracies of my fellow-students. In Dolcoath's wide stopes it was not an uncommon sight to see three or four lusty men swinging sledges the full 'St. Andrew's swing', and beating a drill with rhythmic and accurate precision.

So, whatever Cornishmen have taught the world in mining, the practice of single-jacking would not seem to have emanated from the Camborne district.

Santa Barbara, November 18.

H. E. WEST.

[Has Mr. West ever heard of St. Just?—EDITOR.]

EMERALD MINING is a Government monopoly in Colombia. The best-known mines—the Muzo and Cosquez—are situated in Boyaca about 90 miles north-west of Bogota; a third, the Somondoco mine, is about 35 miles east of Bogota; and a fourth deposit, the Cuincha, across the Minero river from the Muzo mines. The two last named deposits are said to be as rich as the more famous mines of Muzo and Cosquez, but are not easily accessible. The Muzo deposits lie in a valley on a spur of the eastern Cordillera, two or three days' journey on muleback from Bogota over bad trails through rough country. The emeralds occur in veins of calcite traversing black Carboniferous limestone. To follow the veins steel bars and shovels are used to cut down banks, great care being exercised not to injure the emeralds as the veins are approached. No engineering skill can determine beforehand the approximate value of any vein or deposit, but

wherever a vein shows it is followed, even for years, and once a productive formation is found it is worked night and day until exhausted, sometimes over a period of years, as at Muzo.

San Francisco Mint Adopts Electric Furnace for Melting Copper and Nickel

The U. S. Mint placed in operation on November 9 a $\frac{1}{2}$ -ton Rennerfelt electric furnace. This furnace supercedes several gas-heated crucible-furnaces, and is being employed for melting cupro-nickel and bronze mixtures used, respectively, for the five-cent and one-cent coins. The furnace is not being used for melting gold or silver.

The furnace operates on two-phase, 60-cycle current, supplied at 2200 volts by the power company, and stepped down to approximately 110 volts at the furnace. The amperage during a heat ranges between 650 and 800. There are three carbon electrodes. The holders are water-cooled and the arc is regulated by hand. It is probable, however, that this will be superseded by automatic regulation. The furnace has an acid lining and bottom, silica brick and sand being used. It is charged with pigs of copper, nickel, etc., together with crop-ends from the ingots, punchings from the sheets of metal from which the blanks for coins are cut, and other scrap from the coinage operations. On account of the method of operation, however, this scrap is practically as free from impurities as the original metal. No flux is used, but a layer of charcoal is shaken on the surface of the metal in the pouring-ladle to protect it from oxidation.

At the present time the metal is poured into a hand-ladle holding about 100 lb. of metal, and from the ladle into the ingot-molds, which are of steel and are arranged in a sort of circular rack. The molds are made in two halves, which are clamped together. The inside of the mold is swabbed with crude oil to prevent the molten metal from adhering to it. Each ingot is approximately $\frac{3}{4}$ by 3 by 24 in. and weighs about 10 lb. A few minutes after pouring, the ingots are cool enough to permit opening the molds. The ingots are removed and quenched in water, the interior of the molds is swabbed again with oil, and the molds are re-clamped ready for pouring again. After cooling, the ingots pass to the cropping machine where the upper part of the ingot is sheared off. The ingots then go to the rolling-room. This procedure is soon to be modified by the installation of a slow-moving conveyor upon which the ingot-molds will travel. Operations will be timed so that, at the proper interval, the molds will be opened, the ingots quenched, and the molds returned to the pouring-position. A conveyor will also take the ingots from the quenching-tank to the cropping machine. In the rolling-room the ingots are rolled into sheets the thickness of the coins, 22 passes through various-sized rolls being required. The coin-blanks are then punched from these sheets, after which the blanks pass through a machine that turns up the edge. They are then annealed and polished before the final operation of stamping.

Methods of Ore-Sampling in Montana—I

By H. B. Pulsifer

INTRODUCTION. The mechanical sampling of ores has reached a stage of great practical utility, yet, like all other industrial practices, it is subject to change with general progress, as well as from the hints arising in the course of daily work. The following notes will serve to describe certain advanced practices and present conditions, and to suggest directions along which improvement appears promising.

Almost any study of sampling may be resolved into a critical consideration of four phases comprising the basic features of the work. These are precision, cost, method, and equipment. Precision and cost have been placed first in the list because they determine the method and equipment to be used.

PRECISION OF SAMPLING. The degree of precision that is needed or desirable in any one sampling operation depends greatly on the material to be treated and the purpose in view. A combination of good grab-samplings in the mine, at the hoist, and at the furnaces will sometimes suffice if all the operations are under one management and the chemical control is not rigid. This sort of grab-sampling frequently meets the requirements for iron ores, limestone, and coal; it may cost only a fraction of a cent per ton or, at the most, only a very few cents per ton. At the other extreme are the samplings of gold, silver, lead, and zinc ores, which are mined, sold, and treated under the most rigid chemical control and which can well stand a sampling-cost of over a dollar per ton. In the first and most lax type of sampling any one result may not represent the lot to a greater precision than one part in twenty or thirty, yet, because of repetitions and numerous averagings a satisfactory working figure is finally obtained. In contrast with grab-sampling, the more elaborate sampling of the rich metal ores may demand a precision of one part in a hundred at one single operation. There is, of course, much sampling of intermediate precision requiring results to about one part in forty or fifty.

The matter of precision in sampling may be a balancing of sampling effort against uniformity of material; at one extreme comes practically uniform stock requiring very little equalization to secure a representative sample, at the other extreme are materials like high-grade gold and silver ores, which may well require fine grinding and thousands of cuttings to yield a suitable sample. Nearly all the custom sampling-mills in the West handle the ores to give a sample good to one part in forty or fifty by crushing four-fifths of the lot no finer than to two or three inch size and at a cost of from ten to fifty cents per ton.

Rational sampling work demands recognition of two auxiliary operations that are tied in series with the sampling proper as establishing the money-value of a lot of ore. The two operations are the determination of

moisture and the chemical analysis. If the moisture sample is uncertain to one part in fifty or sixty, or if the chemical analysis is uncertain to one part in thirty or forty, or if both are uncertain to about this degree, then it is only a waste of effort to push the sampling precision to greater than about one part in sixty or seventy. It is common to find figures for ore and metal production, extraction, and cost expressed to a refinement of one part in ten thousand, or a million, when neither net weights, samplings, nor analyses are better than one part in seventy-five. Such sequences of figures are impressive only in their absurdity.

A silver-lead ore may be chosen to illustrate the significance of the relationship between the relative precisions in sampling and analysis as affecting the final result. Assume a commercial ore containing about 40% lead and 20 oz. silver per ton. Buyer and seller would like to know the lead and silver contents to within 10c. per ton; neither would care to quibble over an amount smaller than this. It follows that a 10c. fluctuation in the lead means 1.25 pounds, and 10c. difference in the silver means 0.1 oz.; if lead is reckoned at 8c. per pound and silver at \$1 per ounce. One and a quarter pounds is about 0.16% on a 40% lead ore, or approximately one part in 630 parts. A tenth-ounce of silver is 0.5% on a 20-oz. ore, or one part in 200 when stated in whole numbers. It is obvious that only extraordinarily good sampling could hope to approach this refinement and it is even more certain that such a degree of precision is entirely outside the range of commercial analyses. Analysts commonly differ by from 0.5% to 0.8% on a lead determination of a 40% ore when using the same homogeneous sample; they may differ by from 0.2 to 0.5 oz. on a 20-oz. silver ore. A silver determination may reasonably be expected to be trustworthy to one part in forty parts and the lead determination to one part in fifty parts; when put into dollars and cents these limits amount to 50c. per ton on the silver and \$1.25 per ton on the lead. Buyer and seller would, then, be foolish to expect to agree to within 10c. per ton on silver and lead and might with good reason decide to split any differences not greater than \$1.50 per ton on lead and 50c. per ton on silver.

It is here that the ancient bogey of high results by the agents of the seller and low results by the agent of the buyer enters to upset many otherwise good understandings. The trouble will persist until standardized analyses are established. Standardizing of analyses is a difficult matter and is delayed by shortsighted business interests. It is bound to come in due time, however. At present one may affirm that the personal factor is far better eliminated from mechanical sampling than from analytical practice.

No. 1 SAMPLING-MILL AT EAST HELENA

One of the first investigations of the recently established Montana State Bureau of Mines and Metallurgy was a study of the custom ore-sampling plants in Montana. Possibly the most important part of the work as published in Bulletin No. 3 (March 1920) of the Bureau is a test of the precision of sampling as demonstrated by the three most important custom sampling-mills in Montana. These often make repeat samplings on the same lot of ore in the same mill, and once in a while a lot of ore gets sampled in two of the mills, but no lot of ore had ever been sampled in as many mills and as many times as this particular lot. The State Bureau borrowed a 50-ton lot of silver-lead ore containing also commercial amounts of gold and copper. The carload weighed a little over 50 tons and consisted of run-of-mine ore from

a mine within the State. The material was not wholly ideal for the test, but it was the most suitable at that time available and was well adapted to demonstrate the degree of precision to be expected from the mills. The lot contained rather too much fine, yet fully a quarter of it was in chunks over two inches in diameter.

The minerals in the test lot consisted mainly of sulphides in a quartz gangue. The texture varied from large pure grains and sulphide lumps to intimate sulphide mixtures and black earthy powder. The composition was estimated from the analyses to be approximately:

Quartz	30
Pyrite	25
Galena	15
Arsenical tetrahedrite	15
Zinc-blende	5
Other gangue-minerals	10

FIG. 1. ELEVATION OF A SAMPLING-MILL DESIGNED BY THE TRAYLOR ENGINEERING CO.

I quote from my article in the Bulletin:

"The lot typified Montana ore of the better sort, with commercial values in gold, silver, copper, and lead; an ore suitable for demonstrating the precision of sampling on customary and average materials.

"The lot of ore was sampled twice at the Washoe sampler, resulting in two independent final pulps. The lot was sampled in the No. 1 mill at East Helena, using the coarse by-pass; it was tenth-shovel sampled at East Helena, and then finally ground to pass the 2-mesh screens and again sampled in the No. 1 mill, this time in the ordinary way. The lot was sampled once at the East Butte mill while in the coarse condition, but duplicate portions were taken from the mill-product before fine grinding.

"Six different samplings were thus made, giving seven pulps; three different types of mechanical cutters were used and once the lot was hand-sampled. The hand-sampling was first by the tenth-shovel method, and it was then coned and quartered until the final splitting for packets was made with a table-riffle.

"The actual sampling time at the different mills varied; at the Washoe sampler the lot required 20 and 30 minutes at each respective sampling; at the East Butte mill 50 minutes was required for the sampling; at East Helena fully two hours was taken each time the lot was run through the mill.

"The final sampling at East Helena, after crushing to half-inch size, afforded a good standard test, since the material was then all in small sizes, had undergone repeated dispersions and retardations in the mills, and was cut at least 3500 times by each of the mill samplers.

"The lot was sampled in the presence of the author in each instance; no particular arrangements were made at the mills, nor was the sampling carried out in any way differently from the routine procedure which the author has repeatedly observed when he has happened into the mills.

"The seven final pulps were analyzed under as nearly identical conditions as possible in the State School of Mines laboratories. Lest too few results might involve deviations in the chemical work instead of in the sampling, the analyses were checked over from six to eight times so as to furnish average figures for each component. Pulp inequalities, chemical influences, and manipulations all introduce deviations, which repeated analyses alone can eliminate so as to show the precision or lack of precision in the sampling.

"The results of the analytical work follow:

Sample	Silver, oz.	Gold, oz.	Lead, %	Copper, %	Iron, %	Insoluble, %
A	37.8	0.21	12.73	1.74	14.49	32.58
B	37.3	0.22	12.46	1.69	14.43	33.07
C	37.0	0.23	12.50	1.74	14.46	32.87
D	37.9	0.21	12.64	1.78	14.77	32.01
E	37.3	0.21	12.64	1.76	14.52	32.83
F	37.4	0.21	12.72	1.70	14.35	32.50
G	37.5	0.22	12.91	1.73	14.72	32.22

"One conclusion, only, can be drawn from the results in the table: namely, that the sampling was well done in each instance. The difference between the several pulps is less than excellent analysts might report on one and the same pulp.

"The individual items and gross values of the lot may be calculated for each sampling, reckoning silver at \$1.25 per ounce, gold at \$20.67 per ounce, lead at 8 cents per pound, and copper at 18 cents per pound.

Sample	Silver	Gold	Lead	Copper	Total	Deviation from mean
A	\$47.25	\$4.34	\$20.37	\$6.26	\$78.22	+\$0.44
B	46.62	4.55	19.94	6.08	77.20	—0.58
C	46.25	4.75	20.00	6.26	77.26	—0.52
D	47.38	4.34	20.22	6.41	78.35	+0.57
E	46.63	4.34	20.22	6.34	77.52	—0.26
F	46.75	4.34	20.35	6.12	77.56	—0.22
G	46.88	4.55	20.66	6.23	78.32	+0.54

"The total values range from \$77.20 to \$78.35, an extreme difference of \$1.15; the average deviation from the mean of all the totals is \$0.45. Ore-producers should cer-

FIG. 2. TAYLOR AND BRUNTON SYSTEM OF SAMPLING AS USED AT THE WASHOE SAMPLER AT BUTTE

tainly be well satisfied with custom sampling which shows this degree of precision."

Mechanical sampling of the degree of precision indicated will generally be considered excellent work for the sort of material used. The results also bring out an important fact often overlooked, namely, that the degree of precision is a function of the amount of the element determined. In the above table the precision is least on the gold, amounting to one part in 20 on the 0.2 oz. of gold present. If there had been only 0.02 oz. of gold present, the precision might have been no greater than one part

in three. The precision on the silver figures to about one part in forty; the results on the lead, copper, iron, and 'insoluble' are intermediate between those on gold and those on silver.

At Butte, copper ores are considered easy to sample. The copper minerals are fairly well disseminated and, of course, highly brittle. The low grade of the copper ores, from 2% to rarely as high as 10%, is also in favor of both sampling and analysis. Two or three per cent of copper in an ore is low enough to avoid the pitfalls of mechanical

is not considered excessive. After the degree of precision and approximate cost of sampling are established for any given material, one can select the method and equipment best suited for the work. It would be far from true to say that this logical sequence is commonly followed in practice; numerous and unexpected exceptions occur because of customs, habits, available equipment, workmen trained in certain ways only, or from lack of knowledge of better ways.

In the Western States there are probably fifty sam-

FIG. 3. THIRD CUTTER AND THIRD SET OF ROLLS IN WASHOE SAMPLER AT BUTTE

FIG. 4. BRUNTON CUTTER ABOVE CRUSHER AT ANACONDA SAMPLER

sampling and yet large enough for good precision in the chemical results. The chemical determination of copper is, furthermore, one of the most precise commonly made. The experience of the Butte district is that lead, zinc, and silver ores are less easy to sample than copper ores, and that gold ores are the most difficult of all to sample. A Butte copper ore would have afforded a too easy, and thus inconclusive, test of the sampling-mill practice, whereas a gold ore would have been entirely too difficult for a practical test.

COST OF SAMPLING. There are some ores, like iron ores, that are cheap, fairly uniform, and satisfactorily sampled at an outlay of only a fraction of a cent per ton; there are other ores and metallurgical products of such value that an expenditure of a dollar, or more, per ton

pling-mills built to sample copper, lead, and precious-metal ores; these mills were built to displace the hand-sampling by shovel and cone-and-quarter methods as first used or to accommodate the large-scale operations more recently established. They have a decidedly stereotyped design as forced upon them by conditions now more or less obsolete.

The Western ores that needed sampling have usually been of sufficient value to stand a charge of from 10c. to \$1 per ton and justify the construction of permanent and substantial mills. The prevailing blast-furnace smelting of past decades demanded as coarse stock as possible and favored the crush-and-cut method now almost exclusively used in the mills. A further determination of present mill-design came from the former necessity of elevating

stock by bucket-elevators exclusively, and the impracticability of putting more than one crush-and-cut couple on any one floor of a mill. The general result has been that the mills are built very tall, the entire lot is lifted to the very top of the mill, and then loses its elevation by falling from floor to floor, a large part of the fall being wholly lost in simply getting from machine to machine or from floor to floor. Further disadvantage comes from having to distribute power, attendance, and machinery over five or six superimposed floors.

The reasons given may account for the present design of sampling-mills, yet offer no excuse for their not being more efficient, operating at less cost, and being built on more recent patterns. A manufacturer will tell you that there are not enough sampling-mills built to warrant extensive study or the planning of special machinery. He will say that sampling-mills are built only rarely, that the average mill handles only a small tonnage with a scanty treatment, that all the sampling-mills in the country do not amount to as much as one big concentrating plant. There also appears to be something secret about sampling costs and operating data, thus excluding from effectiveness that most stimulating factor in industrial progress, namely, publicity. When a sample-mill has been built and put in service it is then left to wear itself out; they are seldom altered and improved as are concentrating mills. Plans have always called for standard design and standard equipment of the most conservative type.

It is now common for sampling-mills to use belt-conveyors, but largely as adapted to the old idea of numerous superimposed floors. The East Helena plant of the American Smelting & Refining Co. has five floor-levels, although it is a mill elevating solely by conveyors. Why should not the units in a sampling-mill be served by belt-conveyors with all the machinery in line and on one level? The sample-cutters can be placed close under each crushing-unit and deliver the sample to a conveyor elevating to the next rolls. All the rejects can be collected on one and the same conveyor and loaded into cars at the far end of the mill. A mill with the crushing-equipment on one floor should be excellent from the construction, mechanical, and power distribution points of view. One crane could serve all the units and greatly facilitate repairs. Supervision and attendance would be greatly facilitated by a one-floor design.

An incomplete fulfilment of the one-floor design is illustrated in Fig. 1, which is supplied by the Traylor Engineering Co., and is an elevation of a mill designed for the Northport Smelting & Refining Co. In comparison with the Northport mill, whose total elevation covers some 54 ft., may be offered the older scheme of the Washoe sampler, whose total height from lowest elevator-pit to point of roof is 96 ft. One might conclude from Fig. 2, which is the sampling scheme of the Washoe sampler, that the machinery is quite closely spaced and that little elevation is lost; Fig. 3, however, shows the actual spacing of two of the units and demonstrates how 75% of the fall on one of the floors is so much lost ele-

vation. Fig. 4 is a picture of one of the oscillating cutters over its crusher in the Anaconda sampler; there is no lost elevation in this instance.

The ungainly large size of sample-cutters theoretically adequate to handle the first selections in a mill has prevented their use. This source of possible criticism can be closed by placing the cutters immediately below the crushing units in the basement where their large size and awkwardness would not be so conspicuous. There are strong reasons for the insertion of storing and equalizing devices between a cutter and its next following crushing unit. Devices of this sort need occupy only little head-room and would fit in with horizontally arranged machinery as well as the present vertical arrangement.

Straight-line single-bay sampling-mill design ought to decrease the original construction cost by from 25 to 40%, as well as decrease all subsequent operating and maintenance costs by an equal amount. Many mills suffer seriously in capacity, and consequently in the cost of sampling, from delay in unloading cars, especially because of ore in solid bottoms or box-cars, from frozen ore, from muddy ore, from mill-chokes and break-downs; with such sources of expense eliminated one looks to design and economy for the next most feasible improvement. The straight-line design is offered as one suggestion worthy of trial.

The cost of sampling is usually considered an unproductive expense to be held at the lowest possible limit. However, in industrial operations, sampling is as necessary as mining, weighing, or extracting a metal. The cost of sampling is fortunately a minor expense, yet, because in the aggregate it amounts to a large sum, it deserves to be studied as any other cost-factor.

If two men working for 75c. per hour can pipe-sample a 50-ton car of concentrate in 30 minutes, the cost obviously is 1.5c. per ton for the uncorrected item. The cost of pipe-sampling will be greater than 1.5c. per ton because of unproductive time, bucking-room charges, and overhead expense; 5c. per ton is probably a closer figure for the actual expense. Pipe-sampling affords good precision and low cost when the material is suitable. The tendency toward greater production of concentrates instead of marketing raw ores unites with the low cost and precision of pipe-sampling to assure it increasing usefulness in the future.

Crush-and-cut methods of sampling will continue to be used. Probably most Western mills now sample at from 20c. to 60c. per ton, but with better mills and more efficient operation the work should be done at about half the present cost.

(To be Concluded)

TRAVELERS reaching Chihuahua will now be able to secure comfortable and modern hotel accommodations. Electric lights and all other modern conveniences have recently been installed, according to the American Vice-Consul. Rooms can be had for from \$2 to \$5 per day. Table d'hôte meals are served in an up-to-date dining-room at a charge of \$1.50 per meal.

The Sinking of the Alpha No. 2 Shaft at Kimberly, Nevada

By H. S. Munroe

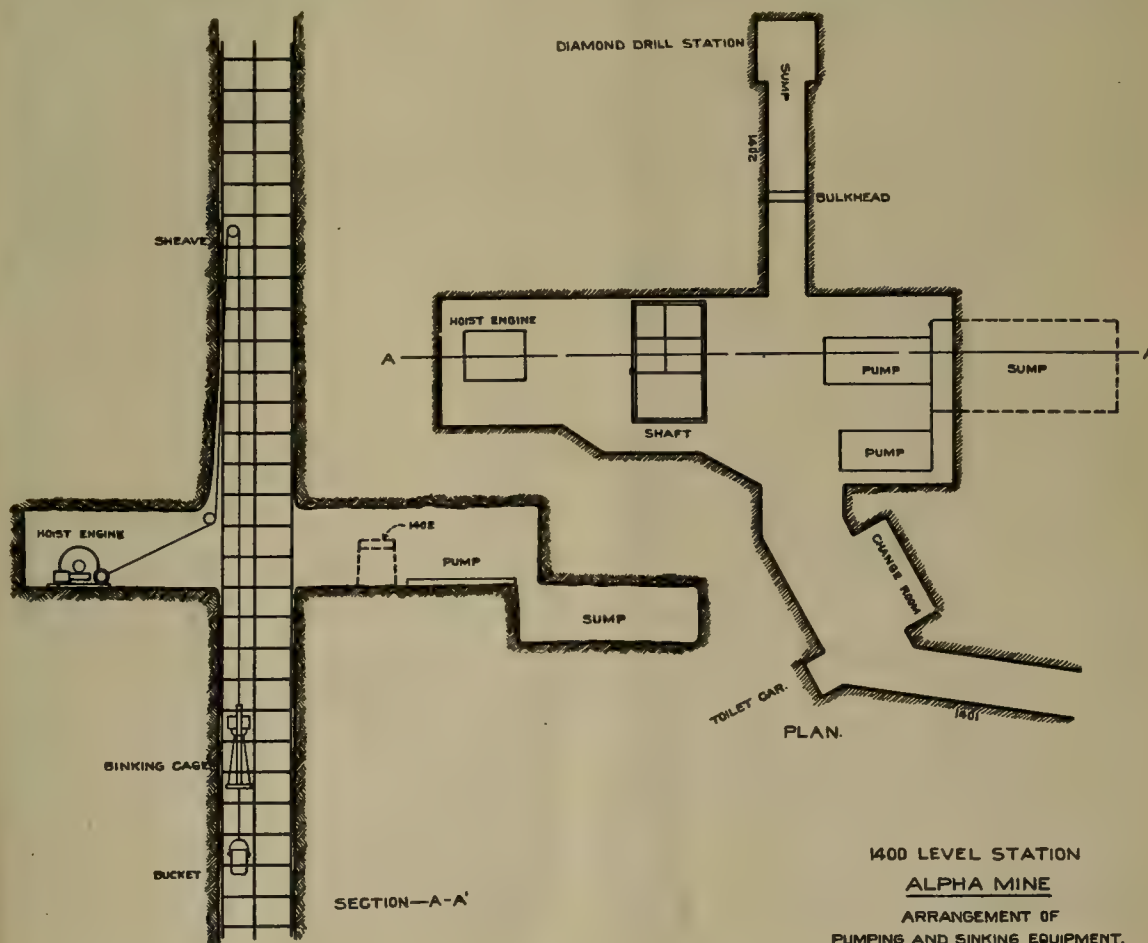

After a diamond-drilling campaign, by the Consolidated Copper Mines Co., conducted from the 1300 and 1400-ft. levels of the Alpha mine, it was decided to sink the main or No. 2 shaft from the 1400 to the 1800-ft. level.

On account of the extraordinary overhead expense involved in sinking from an underground station, and the delay such sinking would occasion to the normal operation of the mine, it was planned to get all possible speed on the job once the work was actually started: first, by providing and maintaining the best available equipment, and, second, by making the wage attractive on a sliding-scale contract so that the good men we hoped to provide would not only stay on the job but would take a lively interest in it, and, third, by making provision against delays that might be caused by the rather heavy flow of water in case of ordinary pump difficulties.

The rock in which this shaft is sunk is limestone, varying from a dense hard blocky phase to more shattered comparatively soft rock. In its shattered phases there is more or less silicification.

The water-level of the mine is at the 1000-ft. level and the normal flow from the 1400-ft. level is approximately 800 gal. per minute. Of this amount all but 100 gal. per minute originates in the altered ore-bearing zone, which is at an average distance of 500 ft. north of the shaft. The mine is kept free of water by compound-condensing steam-pumps, which are not over-capacity and are subject to occasional stoppage. To provide against delays occasioned by pump-stoppages, a concrete bulkhead with regulating-valves was established on the 1400-ft. level. This installation was utilized on five occasions during the four months of sinking.

On account of the position of the pumps and sump on

the skip side of the shaft on the 1400-ft. level, it was impossible to cut a loading-pocket on that side. Similarly, on account of the sinking-compartment (designated on the sketch as 'manway') and the pipe-way intervening between the sinking-station and the skip-ways, it was equally impossible to provide a pocket for direct loading into the skips from the sinking-station. It was necessary therefore to revert to the time-favored Butte custom of installing hinged doors at the collar of the sinking-compartment. The buckets were dumped directly into cars run onto these doors.

A 10 by 14-in. air-operated geared hoist with two 300-

ing and this mud was sluiced directly into the skips as provided for in the construction of the bulkhead.

The matter of personnel was given careful attention. A crew of 18 experienced shaft-men was picked for this work. It is an interesting fact that only two men changed during the entire period. These men worked on a sliding-scale contract and made attractive wages. The crew, per shift, consisted of six men in the bottom, one of whom was rated as a shift-boss and received one dollar per shift in addition to his contract wages. In addition, there were one pump-man, two bucket-dumpers, and one hoist-engineer per shift, all of whom worked on

day's pay. It is believed that the men in the bottom augmented, from their earnings, the pay of the others. There was excellent co-ordination of effort between the men on a given shift and keen, though friendly, competition between the three shifts. It would be hard to imagine more harmonious working conditions.

Sinking started on November 12, 1919, and was finished on March 5, 1920, the operation having proceeded without any delay worthy of mention and without any serious accident. Much credit for the net result is due R. B. Brown, mine foreman in charge of operations at the Alpha mine.

ALPHA No. 2 SHAFT. ACTUAL DIMENSIONS; TIMBERS SIZED

cu. ft. air-receivers was installed at the sinking-station. A specially designed light-weight sinking-cage with 12-ft. extension-shoes was provided. A 20-cu. ft. bucket, of which three were provided, was suitably suspended from the deck of the cage.

For drilling, Denver Rock Drill Co.'s No. 59 'Clippers' were provided. These drills were new at the start of the sinking and were taken on top and completely overhauled after each round. At least one spare drill was kept on the sinking-station during the drilling shifts to ensure against delays. No delay on account of drill failure was recorded.

Water from the bottom of the shaft increased from 40 gal. per minute at the start, to about 140 gal. per minute at the finish; it was pumped by No. 7 and 9B Cameron sinking-pumps, of which a spare was kept available on the sinking-station at all times. To provide for the settling out of the worst of the solids in the water from the shaft, the diamond-drill station shown as 1402 in the sketch, was converted into a sump by the construction of a bulkhead; from behind this bulkhead the water overflowed into the main pump-sump. The auxiliary sump filled with mud several times during the period of sink-

A statistical table covering this operation follows:

Feet advanced	400
Mine-shifts worked	312
Man-shifts worked (in bottom)	1,812
Total time:	%
Drilling	18.9
Blasting	7.3
Mucking	49.6
Timbering	16.2

Objectionable Practices of Minerals Separation

By George L. Nye

*The day of the bonanza is gone. The mining of the metals has developed into an industry in which economical treatment of large tonnages of low-grade material and the elimination of waste are the important features. The evolution of mining has produced a corresponding change in the manner of ore-dressing and ore-concentration.

Experimenters and investigators have been steadily in the field, and as far back as 1884, they were seeking to take advantage of the well-known affinity between metallic particles and oily substances, plus the buoyancy of oil in water, as a means of separating metal from gangue. Experiments and investigations were constant and widespread, but no satisfactory process, that is, none that was at the same time both efficient and economical, had developed until fifteen or sixteen years ago, when four processes came into commercial use, at practically the same time, in the Broken Hill district of Australia. They were known as the Potter-Delprat, the De Bavay, the Minerals Separation, and the Elmore vacuum processes.

The Potter-Delprat process, since acquired by Minerals Separation, consisted, in a general way, of the introduction of a fine ore-pulp into a pointed box containing hot sulphuric acid or hot salt-cake solution. There was a resulting reaction on the calcium carbonate in the material, producing a great quantity of bubbles, which attached themselves to the sulphide particles and raised them to the surface in a thick coherent froth.

The De Bavay process made use of the 'floating greased needle' idea, but, instead of making a coherent froth, there was a thin film of mineral particles floated off the top of the vessel.

In the Elmore vacuum process, the material to be treated was thoroughly mixed with water, oil, and acid, the combination being then drawn into the apparatus by a suction-pump. The suction released the pressure of the pulp, with the result that nearly all the oil dissolved in the water escaped the solution in the form of bubbles, which attached themselves to the sulphide particles and raised them to the surface in the form of a thick coherent froth. In some instances, calcium carbonate was added to the material.

In 1905 the Sulman, Picard, and Ballot patent, which formed the basis of the process being operated by Minerals Separation, was taken out in England. The same process was patented in the United States in 1906, and is known as patent 835,120, being the patent litigated in the now celebrated Hyde case.

*A paper read before the American Mining Congress at Denver on November 17, 1920. The author is of counsel for the Mining Congress in the proceedings against Minerals Separation before the Federal Trade Commission. The footnotes have been added by the Editor.

In 1905, 1906, and 1907, although the processes mentioned were commercially operating in Australia, but little was known about them in the United States, and it was not until after the patent application of Sulman, Picard, and Ballot, which later became patent 835,120, was applied for, that the use of oil-flotation as a commercial method of ore-concentration was introduced into the United States.¹ The interest aroused was immediate and wide-spread, but the development of the art and its application to commercial uses was not at all in accord with either its possibilities or its opportunities.

Mining-men, the country over, have been free to criticize the policy and practices of those controlling the fundamental patents, who apparently have been desirous of commercializing their ownership, while preserving their knowledge and information as trade secrets.

In taking this attitude, the patent-owners have entirely lost sight of the fundamental basis for patent laws of the United States, found in the constitutional grant of legislative power to Congress, in the following language:

"To promote the progress of science and the useful arts by securing for limited terms to authors and inventors the exclusive right to their respective writings and discoveries."

Referring to this constitutional provision, the Circuit Court of Appeals of the Third Circuit in *National Harrow Company v. Hench*, 83 Fed. 36, said:

"It is no part of the constitutional scheme or of the patent laws to secure to inventors a profit from the suppression of their creations."

In proceeding contrary to the spirit and intent of the constitutional and statutory provisions as interpreted by our courts, Minerals Separation has resorted to many practices criticized and condemned by the mining fraternity.

These practices may be summed up as follows:

It has suppressed technical information, thus retarding the development of the art.

It has made indiscriminate charges of infringement and has failed at the same time in many instances to point out any infringement.

It has required independent inventors and manufacturers to pay commissions on sales of their own apparatus.

It has discriminated unfairly in royalty charges, has charged and is charging excessive royalties and seeking to fasten such royalties upon the operator beyond the life of its patents.

It has made excessive claims to flotation rights, falsely

¹The process of patent 835,120 was not applied in this country by Minerals Separation until 1915.

disparaged independent apparatus and threatens lawsuits to coerce operators to sign a license contract.

It compels engineers in its employ to sign illegal and iniquitous contracts, and requires licensees and their employees to assign their inventions to it.

It has injected spies and hirelings into the plants of operators refusing to take out a license; and it has violated the criminal laws by breaking and entering the premises of another and threatens to continue such practices, justifying its actions by its alleged necessities.

SUPPRESSION OF TECHNICAL INFORMATION AND RETARDING THE ART

In 1909 and 1910, there was a great scarcity of information concerning flotation, even in London where the process was supposed to have been invented some four or five years earlier (R 1624-40).

At the office of Minerals Separation it was stated that they did not care to give out information. There were no books on the subject and the practice of the art was shrouded in secrecy.

When Theodore J. Hoover sought to publish his book, he was violently opposed by Minerals Separation, which, however, later gave a reluctant consent, and the book finally came out, minus certain excisions insisted on by Minerals Separation (R 1642-3). The excisions, according to Mr. Ballot, were considered necessary in the company's commercial interests (R 563). Private profit had even then begun to outweigh public interest in the prosecution of science and the useful arts.

Dr. Gregory sugar-coats the pill by calling it "self-protection". He says (R 621-2-3):

"I am looking at it purely from a moral standpoint—I would say it was an absolute dereliction of duty on my part if I allowed any employee of ours to go and ruin the prospects of a company just because he wanted to air his views."

He adds, however, that in some instances:

"Where we have been able to satisfy ourselves that it would be innocuous we have allowed it (the publication of information), but it has done us harm nevertheless."

John Ballot, president of Minerals Separation (R 561-565), says:

"Our policy is this: with a company developing and exploiting patented processes, we have licensees using these processes, and we are obligated to pass improvements and inventions on to licensees for use. We are not satisfied with the finality of our process as an invention; apart from exploiting the processes commercially we also try to improve them to make them still more useful. Our business, therefore, is of a secret nature. If we permitted our staff members to write papers and discuss things publicly, what possible chance would there be for us to develop our patents."

In other words, for the sole purpose of facilitating private commercial exploitation of a patent right, Minerals Separation suppresses all information which might be used as a starting point for further development of the art by any one of a thousand brains outside its employ.

All this in the face of the fact that it has been the settled law of this country ever since the decision of the Supreme Court of the United States in *Pennock v. Dialogue* (2 Peters 1):

"That the primary purpose of our patent laws is *not* the creation of private fortunes for the owners of patents, but is to promote the progress of science and the useful arts."

Dr. Gregory admits (R 624-5) that:

"There is no authoritative work on flotation, either in America, England, or Australia, no book on flotation that I would consider an authority."

If any further proof of the desire and effort of Minerals Separation to suppress information be required, it is found in the fact that some years ago when a publisher² was about to print an interview with a prominent metallurgist, formerly a licensee of Minerals Separation, the latter's chief engineer threatened "to raise a red flag" if such publication was not suppressed. When crowded for a reason for his attitude, his only answer was that the author said something about the treatment of concentrates by chloridizing roasting and leaching, and he was thinking of taking out a combination patent for that, himself.

Of course, every one at all familiar with the industry knows that such methods of treatment had been almost in common use for more than a quarter of a century.

That this attitude of Minerals Separation has unquestionably retarded the advancement of the art is affirmed and asserted by practically every mining-man and mill-man who has come at all in contact with the situation.

A well-known San Francisco editor,³ himself an engineer of wide experience, says (R 1650-51), referring to the advancement of the art in this country:

"It has been extremely slow considering the importance of it. The progress of the art in this country has been retarded by the attempt to impose secrecy upon the experiments and the operations of those using the process by means, of course, of these license agreements and other methods, but more particularly by the effort to tie individual metallurgists to the chariot-wheels of this patent exploiting agency."

Government officials⁴ connected with the Bureau of Mines express it as their opinion (R 2067 and R 2395-6), after years of experience and careful observation, that the attitude of Minerals Separation has been to retard the development of the flotation art.

One Bureau of Mines man⁵ (R 2053-65) has observed and noted a number of instances where mining companies have refused to consider an additional saving by the installation of flotation because of the repressive tactics practised and the license agreement tendered by Minerals Separation.

²T. A. Rickard, of the 'Mining and Scientific Press'.

³Ibid.

⁴Thomas Varley, superintendent Salt Lake Station, Bureau of Mines, and others.

⁵Ibid.

INFRINGEMENT

In one thing at least, Minerals Separation has at all times dealt with lavish hand, that is, in its indiscriminate wholesale charges of infringement. The company's own records show that it has carried in its "infringement file" hundreds of operators, individual and company, who have never used flotation at all, and in some instances, concerns that have not even had a mill on their property.

Their chief engineer⁸ admits that they get most of their information concerning infringement from the technical press and casual information (R 1240, 647). This information is passed on to patent attorneys who send out notices of infringement and threats of suit without further proof of the fact (R 1248). This same engineer admits that not nearly all of those listed as infringers are actually operating flotation (R 1268-9, 1275-78).

Apparently the plan was not only to reach the actual operator, but to throw a fear into the prospective operator at the same time.

The 'holier than thou' attitude of Minerals Separation is well disclosed by the statement of its engineer (R 1212-13-14); in referring to the action of the manager⁷ of a certain company, who, he says:

"Came and said that they wanted to take a license with us and settle up for their sins."

and adds:

"He was sinning against the law of using flotation illegally. His statement was the result of a letter which Mr. Henry D. Williams sent around generally to those on the list. They were our list of infringers."

These threatening letters from Henry D. Williams were sent to experimenters (Westcott R 1860), to those using the Callow process (R 1894 Lambourne) and to those operating outside the limits of patent-right awarded in the Hyde case (Hollister R 2330-31). Similar threats were made by representatives in personal interviews (R 1894-2396), yet so far as we have been able to ascertain, the threats were all based upon the broad and all inclusive proposition that Minerals Separation *controls flotation*.

The chief engineer says (R 1152):

"The scope of our patent has been discussed by me with infringers in a general way in that I told them that our patents covered the commercial use of flotation, and that we proposed to enforce our patents . . . Advice to field men has been in a general way that people using flotation are probably infringers."

He also says (R 1247):

"Our investigators went to the operators and obtained information. They did not report what patent was being infringed. They haven't any idea of patents. We have these operators down on our infringing list . . . The elements entering into flotation process which in general infringe our patents are agitation and aeration, and the

use of oil and other reagents with the formation and separation of froth, all in an ore pulp containing mineral values."

One of Minerals Separation's field representatives admits that in many instances (R 1828-35) neither the apparatus nor the reagents used were disclosed and yet the operators were classed as infringers.

The former manager⁹ of the Midvale Minerals Co. in Utah reports (R 1877) that the representative of Minerals Separation who called on him "got into the subject of infringement immediately".

"He did not state or point out in any way whatever the manner in which we were infringing, but claimed infringement merely by use of flotation. He (R 1885) talked about suits that Minerals Separation had brought against other parties, and was careful to state that all of them had been decided in favor of Minerals Separation."

Another mine manager⁹ was informed (R 1897) that the company was going to give the smaller operators "their due", later on.

Still a third¹⁰ (R 1954) was told that suits were being brought on other points than the amount of oil used, and that after the decision of the Supreme Court, Minerals Separation was "going after the protection of their rights".

Another manager,¹¹ using more than 1% of oil on the ore (R 2326) was told that he was infringing. The representative did not say how, but insisted that flotation could not be used without infringing Minerals Separation patents.

I have given a few of the instances where wholesale charges of infringement without specification, and threats of litigation without actual suits, have been used apparently to intimidate and frighten the small operator.

INDEPENDENT INVENTORS AND MANUFACTURERS

Another branch of the "exploiting" business upon which Minerals Separation embarked originally, with great eclat, was that of requiring independent inventors and manufacturers to pay commissions on sales of their own apparatus. True it is that this practice has now, in the main, been abandoned, but the facts concerning its pursuit while it lasted are interesting and extremely illuminating in a consideration of the acts and doings upon which this patent exploiting agency is thriving.

In December 1916 (R 1358-78-Exhibits 249-259, inc.), the Stimpson Equipment Co., handling the Janney machine, designed to be operated in flotation concentration, was advised by a prospective purchaser¹² that Minerals Separation was threatening trouble if the purchaser put Janney machines into operation. This naturally caused the Stimpson Equipment Co. to investigate the matter,

⁸George T. Hansen.

⁹George W. Lambourne, general manager for the Judge Mining & Smelting Co.

¹⁰O. J. Salisbury, of Salt Lake City.

¹¹William C. Hollister.

¹²Engels Copper Co., of San Francisco.

⁶E. H. Nutter.

⁷J. W. Hutchinson, of the Goldfield Consolidated Mines Co.

and to request that the attitude of Minerals Separation be disclosed.

Later Minerals Separation was advised that the prospective purchaser was one of their licensees, so that the sale could in no manner contribute to infringement. Stimpson¹³ was informed, however, that the chief engineer¹⁴ would see him on his way West, and later was requested to meet the engineer at Ogden, Utah. The meeting occurred, and the engineer then tendered to Mr. Stimpson a memorandum of a proposed contract that might be entered into between the Stimpson Equipment Co. and Minerals Separation regarding the sale of Janney machines. The memorandum was handed to Mr. Stimpson (Ex. 250).

This memorandum is one of the most astounding documents that has ever found its way into print. It provides that Stimpson shall have the right to sell the Janney machine to Minerals Separation's licensees, but requires that he agree not to sell, rent, or lease any flotation machine except to such licensees. It stipulates that Minerals Separation must have a contract enforceable by injunction, and that it (Minerals Separation) shall become sole licensee to sell the Janney machines, but that it will, in turn, appoint the Stimpson company selling-agent. It stipulates that orders for Janney machines must be O.K.'d by Minerals Separation before machines are shipped, and requires that it receive 25% of the gross profit made between net manufacturing cost and selling price.

Naturally such a contract was not acceptable to the Stimpson Equipment Co.; after objection and considerable correspondence, a new form of contract was submitted, which Minerals Separation's chief engineer declared would not violate the anti-trust laws, but this contract contained a provision for a heavy penalty in the event that any machines manufactured by the Stimpson company were used in infringement of Minerals Separation's process-patents. In other words, the effect of the penalty was to close the door to any customers for the Stimpson Equipment Co. except licensees of Minerals Separation. The proposed contract was not signed.

Jackson Pearce,¹⁵ another machine manufacturer, was told by Chief Engineer Nutter that anyone who used one of his machines and infringed, would make him (Pearce) liable (R 2296). Pearce refused to sign the contract submitted, objecting to the clause requiring payment of 10% of the selling price to Minerals Separation and fixing a liability of \$10,000 in the event that any Pearce machine was used in infringing operations.

A similar contract was offered to Mr. Ruth,¹⁶ another manufacturer. It was stated at the time by the chief engineer that the contract was the standard form (R 2410) and that he, Ruth (R 2414), was not only an infringer, but worse than an infringer, for he was "furnishing the

brains for other men to infringe with". Ruth was also told that he was making a living illegitimately (R 2417).

ROYALTY CHARGES

In February 1915 the assignor of Minerals Separation North American Corporation entered into a special contract with the Anaconda-Inspiration group, and in June 1916 special royalty terms were given to the Colusa Parrot Mining & Smelting Co., because the quality of its dumps, the low recovery, and the narrow margin of profit to the company, made such terms equitable in the opinion of the assignor (R 501).

A special agreement was also made with the St. Joseph Lead Co., the Doe Run Lead Co., and the Desloge Consolidated Lead Co. (R 905).

Dr. Gregory explains (R 908) that the licenses issued to these particular companies were special because containing a condition that they would pay a certain sum whether they treated ores or not.

President John Ballot (R 513) explains that in the instance of the Colusa Parrot company the contract provided for a royalty of 6c. for twenty pounds of copper recovered and that his company rebated 3c. He says (R 515):

"We merely agreed to leave the license as it was, the license taken up at a certain rate of royalty. As the royalty was paid and payable we refunded half of it to the owner. The agreement was probably oral, at most an exchange of letters."

It is stated (R 537) that Minerals Separation, in settling with infringers, has adopted the policy of charging the infringer who comes to the office and confesses infringement, double the amount he would have paid if he had taken out a license; then after he had paid for past infringements he is treated and put on the same basis as everybody else who has a standard form of license—he cannot, however, get the Anaconda agreement.

This was the attitude and stand upon which Minerals Separation, in August 1915, tried to avoid a previous agreement with Utah Leasing Co., saying (Ex. 303, Ex. p. 2242):

"The London Board refuse to agree to the 6c. minimum royalty . . . and insist that this material pays a flat royalty of 12c. per ton. This on account of the fact that to grant you this 6c. minimum would jeopardize our contract with the Anaconda Company."

and yet in November 1915 a special contract was granted the St. Joseph Lead Co., the Doe Run Lead Co., and the Desloge Consolidated Lead Co. "with the consent of London", which had "the identical terms accorded Anaconda in their license and private agreement."

It also appears that for several years Minerals Separation was charging one company 50c. per ounce of gold recovered by flotation concentration and another company using substantially the same methods and treating substantially the same character of material during the same interval was charged 25c. per ounce.

It must have been punishment or special privilege, one or the other.

¹⁴Mr. Nutter.

¹⁵Jackson A. Pearce, of the Argo mill, at Idaho Springs, Colorado.

¹⁶Joseph P. Ruth Jr., of Denver, Colorado.

EXCESSIVE ROYALTIES

There can be no question but that the royalties charged by Minerals Separation are excessive. They are in practically every instance based upon metallic recovery; in other words, upon gross recovery from ores treated.

In one instance a company during its operations in 1917 made a handsome profit, about \$550,000, and paid Minerals Separation a royalty of \$18,652. The following year the same company made a profit of \$50,000 and paid Minerals Separation \$30,000 in royalties. The third year the same company made a loss of \$70,000, but nevertheless paid Minerals Separation \$32,800.

If the fees paid for the use of a process bore some relation to the net amount of profit made by the operator, they might show some elements of fairness, but when charges are made upon a basis such that Minerals Separation gets its profit when the use of its process contributes to a loss upon the part of the operator, as well as when he makes a profit, there is something unfair and inequitable if not illegal and illegitimate in the royalty charges.

Field engineers for Minerals Separation have repeatedly reported (R 1766-1832-3) that operators protested royalties as excessive.

Mine-operators all over the West (R 1917-1952-2062-2063 and Ex. 352-2064 2290-2293-2312-2455-2471) protest the excessive royalty charges, characterizing them as prohibitive, and in many instances refrain from using the process because of such charges.

In one instance, after holding out the prospect if not actually promising, a royalty of 4c. per ton of tailing treated, Minerals Separation demanded 6c. per ton, and after tendering a contract upon that basis and selling, to the prospective licensee,¹⁷ Minerals Separation flotation machines, which the licensee fully paid for, later demanded a flat royalty of 12c. per ton upon the statement that a minimum of 6c. would jeopardize their contract with the Anaconda company. The licensee refusing to be boosted a second time, Minerals Separation took the high-handed procedure of refusing to deliver to the licensee the machines which it had bought and paid for, as a coercive measure to produce an acquiescence in an extortionate royalty. In this they were entirely unsuccessful (R 2097, et seq. Witness Strange and Ex. 275 to 345).

The matter finally wound up with the most astounding suggestion from the representatives of Minerals Separation, namely, that the licensee should sign both the 6c. and the 12c. agreement, submit them both to Minerals Separation for a decision, and entrust themselves and their contract to a concern which was then, in violation of decency and fair dealing, withholding the machinery which the prospective licensee had bought and paid for.

Is it any wonder that the licensee brought a replevin proceeding to obtain possession of its own, and that Minerals Separation ultimately failed in its attempted hold-up?

Under the terms of the license contract put out by Minerals Separation, every licensee is bound not only to give every invention or discovery made during operations under the license to Minerals Separation, but to bind its employees to assign and transfer any such discovery or invention. The licensee also agrees that he will not without the written consent of Minerals Separation during the continuance of the license use or employ any improvement, modification, or addition to any of the inventions specified in the letters patent within the license which is not the property of Minerals Separation.

Dr. Gregory, referring to the contract of the licensees, says (R 580):

"Now coming back to the contract as I said before, one had difficulty in that direction because it was considered that this contract never terminated, but when I explained to them that this was merely an option, and if you used the process you paid, and if you did not use the process you were as good as not having a contract at all, there was no objection of any kind. We simply made the contract, and said, 'Now go ahead, if you find it convenient for you to use the process you pay us a royalty.' The agreement terminates upon their ceasing to use flotation and it commences again when they start to use it."

In other words, when once signed, the contract is perpetual, and extends the payment of royalties beyond the life of the patent right.

The charge of exacting excessive royalties was confessed by Chief Engineer Nutter when he wrote to Minerals Separation in March 1917:

"I am becoming more and more convinced that our royalties are too high and am getting together data which I think will show that we are losing out financially through charging a royalty which is considered too high. The only argument that I can see is that by maintaining our present position we can hold the Butte and Superior Company up for more than we otherwise might."

EXCESSIVE CLAIMS OF FLOTATION RIGHTS

The chief engineer of Minerals Separation thinks (R 1156) that "any use of oil infringes Minerals Separation patents". "All users of flotation (R 1160) are infringers", or, (R 1144) "probable infringers".

He told Manager Martin¹⁸ of the Ozark company (R 1178) that Minerals Separation patents covered "flotation process", that is, all manner of flotation concentration. He keeps all those using flotation on the infringers list (R 1129) upon the general theory that they could not be using flotation in a commercial way without infringing, and says, (R 1267) that it is practically impossible to use oil in flotation concentration without infringement. Furthermore (R 1230) he regards all manufacturers of machines as contributory infringers.

In talking with Jackson Pearce, who was himself the manufacturer of a machine for use of flotation, Chief Engineer Nutter said:

"You are furnishing the brains for other men to infringe with. If they hadn't the flotation machine they couldn't infringe and that would eliminate them. I sup-

¹⁷The Utah Leasing Co., at Newhouse, Utah.

¹⁸George A. Martin.

pose you are aware of the fact that our patents control any number of them. Our patents carry us up into the year 1935, and for fellows like you who are making flotation machines, we have a contract whereby you can manufacture without infringing."

He then offered Mr. Pearce a contract similar to that proposed to the Stimpson Equipment Co. requiring that he only sell his machines to Minerals Separation licensees and pay them 10 or 20% of the selling price for the privilege of being thus restricted in his market.

FALSELY DISPARAGING INDEPENDENT APPARATUS

One of the methods formerly in use by Minerals Separation to coerce the manufacturer of independent flotation machines and compel them to come in and transfer all their rights to Minerals Separation and take in return a mere selling-agent's contract, was to use an ordinary expression, to 'knock' such apparatus and in every way to disparage the same, in the minds of prospective purchasers.

When the Engels Copper Co., late in 1916 and early in 1917, (R 1416) was thinking of installing Janney machines, the representative of Minerals Separation advised the president of the Engels company that before he installed Janney machines he must procure the consent of Minerals Separation, frankly stating, however, that he did not think that the operator could get such consent. When asked what would happen if the operator went ahead without the consent, the reply was that very possibly his license *would be revoked*.

In another instance, one of Minerals Separation's own representatives in the field, in calling upon an operator engaged in installing independent apparatus, had "instilled doubt in his mind that the Hyde machine which he is installing in one of his mills would do the work". (Ex. 157, Ex. page 1476.)

In yet another instance, the Ohio Copper Co. in Utah was using flotation. They had installed a Janney machine and had had the same in operation for about 60 days before a Minerals Separation machine was installed. The mill was treating copper ores which in solution naturally corroded any metallic iron with which they came in contact. The Janney machine was of metallic construction, and at the end of 60 days was naturally less efficient in operation than when new. After the Minerals Separation machine was installed, the two machines were operated concurrently and of course a record of the results was kept. Alfred Frank, manager for the Ohio Copper Co., (R 2557) states: "I did not consider there was any definite period during which there was a test." Notwithstanding this situation, Minerals Separation attempted to make capital and to disparage the work of the Janney machine by circulating unfair comparative results in operation (R 1691 and 4) and this in the face of the fact that the manager for the Ohio Copper Co. states that "the Janney machines did slightly better metallurgical work".

Minerals Separation representatives have repeatedly proclaimed the desire to be of assistance to operators, and always use that as an introductory statement in ap-

proaching anyone thought to be infringing, but their ardor to be of assistance cools rapidly after a license is taken out and actual help is often entirely missing.

One notable instance was the experience of the Chichagoff company, where, after repeated effort (R 1399, 1402) to get help from Minerals Separation, they gave up in despair and went to independent experimenters, who quickly gave them a solution that raised their savings 16%.

THREATENING LAW-SUITS TO COERCE OPERATORS

Dr. Gregory says very plainly (R 601) that a licensee is insured against law-suits. The inference is perfectly obvious. Anyone using flotation who is not a licensee is manifestly in danger of litigation. This is particularly emphasized in a letter sent out by Minerals Separation's patent attorney in which he stated:

"You are hereby notified of infringement of my client's patents . . . You are hereby directed to send me a full statement of your infringing operations . . . In default whereof I am instructed to bring suit against you for an injunction, profits and damages, including a preliminary injunction at the commencement of the suit to immediately stop your operations."

According to the statement of Minerals Separation's chief engineer, such a letter was sent out to 250 or 300 operators, when confessedly not more than one-third of them were actually infringing.

One of the field representatives on one occasion called upon the Idaho Mining, Reduction & Transportation Co. at Idaho Springs, Colorado, (R 1740). This enterprising and energetic young man stated to the superintendent:

"We are checking up the infringers, trying to keep them out of metallurgical difficulties and endeavoring to get them to come in and take out a license to avoid any disagreeable business that might follow."

This representative thereafter very naively stated: "He understood that meant litigation."

Another instance, that of the East Butte Copper Mining Co., after receiving the threat of litigation from patent counsel already referred to, took the matter up (R 2371-3) with their own counsel, and reached the conclusion that they could not afford to get into a fight with Minerals Separation "not because we felt they were in the right—but simply as a matter of expediency".

Then there was the case of the Evergreen Mines Co. (R 2332), absolutely deterred from operation by threats of litigation by Minerals Separation. Their property today is lying idle under a resolution by the stockholders of the company to the effect that they will not re-open the property and commence active operations until they can receive fair and decent treatment from the patent-exploiting agency.

COMPELLING ENGINEERS IN ITS EMPLOY TO SIGN ILLEGAL AND INIQUITOUS CONTRACTS

Theodore J. Hoover, one-time general manager for Minerals Separation, who signed one of their engineer employee's contracts, by the terms of which Minerals

Separation seek to bind the engineers to them not only during the period of their employment, but for all time, characterized the perpetual obligation contract (R 1585) as unjust, immoral, and illegal.

The clause of the contract in question, reads: (R 1589, Hoover, Respondent's Ex. 9).

"He shall also pledge himself to keep in absolute confidence all information acquired regarding the company's business and processes during the time of his engagement, and also afterwards."

The words "and also afterwards" constitute the particularly objectionable features of the contract.

Hoover says (R 1584) that his career has been hampered and rendered difficult for years by those words and by the attempts of Minerals Separation to enforce them.

Mr. Hoover finally sought and obtained the opinion of eminent legal counsel to the effect that such a contract was unjust, immoral, and illegal (R 1582).

Minerals Separation also seek to stop the mouths and hamper the efforts of every metallurgist who enters the employ of a licensee, by forcing upon them a contract similar to that which they enforce upon their immediate employees. (R 1652 *et seq.*)

COMPELLING LICENSEES TO ASSIGN THEIR OWN INVENTIONS TO MINERALS SEPARATION

Clause 3 of the license contract, is the clause requiring licensees to assign their own inventions and improvements and the inventions and improvements of their employees to Minerals Separation.

Dr. Gregory very lucidly (?) explains (R 616 to 19) the intention of this clause of the contract. He says in effect that it is intended merely to procure for all their licensees the benefit of new inventions without extra charge. He fails, however, to make mention of the fact that each time a new invention is made by a licensee and turned over to Minerals Separation for inclusion within the list of patents under its control, that the chains of the licensees are forged anew and the period of their slavery extended for the life of such patent.

Many licensees and prospective licensees complain bitterly of this clause of the contract. One of them¹⁰ characterizes it as "giving a warranty deed (R 1917) on the brains of our organization", and all object to being obliged to release the results of their own investigations and efforts to Minerals Separation for its sole benefit.

In 1917, after writing to the company suggesting that royalty charges were too high, Chief Engineer Nutter said:

"Another matter which is in my mind now and which I will mention here—although it does not properly belong in this letter—is this: that it would be better policy for us to delete from our license those clauses which always cause irritation to our licensees and in practise are not observed. I refer more particularly to the embargo on information and to the binding of employees to turn over inventions to us."

This statement of Mr. Nutter is important for two reasons, first, as a confession that the company has an embargo on information and requires its employees to turn over inventions; and, second, because he recognizes and asserts that as a matter of business policy the company is making a mistake.

USING SPIES AND DETECTIVES IN PLANTS OF OPERATORS

Dr. Gregory tells (R 653) how Chief Engineer Nutter went right into the plant of the Butte & Superior company. He says they had the doors locked, but Nutter broke in—it was "absolute robbery"—and took some of the stuff (concentrate), and put it into a bottle. "If you get some of the froth you know what they are doing," and then added with the utmost *sangfroid*:

"You have to get a thief to catch a thief."

This characterization of their chief engineer may or may not be entirely acceptable to him, but up to date he has been sufficiently mindful of his complete ownership by Minerals Separation, so that he has made no complaint.

President John Ballot says that they have had occasion, and, unless they are ordered to the contrary, they may have occasion in the future to employ men who will use their ingenuity and skill to get into places and find out what people are doing. "We have to use all the modern methods that everybody uses—detectives. We employ a man to go into the works, anyone that we can get hold of to do the business. We employ a man to go into the works and pay him. Detectives were sort of workmen."

In other words, they employ men outright in the first instance as spies, put them under salary, induce them to go to various operating companies and misrepresent themselves as honest men seeking employment, and thereby worm themselves into the works of an operator, taking their money from such operator as regularly as they get their pay from Minerals Separation for the sole purpose of spying out and reporting the operations in that particular mill.

It is brazenly admitted (R 779) that they had a chief spy located in Salt Lake City, who recommended other spies (R 769), who were employed in at least two instances, and who were characterized as the "northern observer" and the "southern observer". He says, however, (R 773) that they were employed to ferret out instances of stealing, and adds:

"By stealing we mean that they were suspected of illegally using our process patents."

These observers were employed at a total cost of a little less than \$10,000.

The arch conspirator, reporting to president Ballot, (Ex. 83, Ex. R. page 1161), says:

"I just want to inform you that I have secured, by devious and most unethical means, a sample of X-cake which I am sending by registered mail to Mr. Higgins today."

When we consider the suppression of information, the indiscriminate charges of infringement, the demands

¹⁰George W. Lambourne, of the Judge Mining & Smelting Company.

upon independent inventors and manufacturers, the excessive claims to flotation rights, the disparagement of independent apparatus, the threats of coercion, the strangle-hold contracts imposed upon licensees and employees, and the excessive and discriminatory royalties which are being charged, to say nothing of the outrageous methods employed by this patent-exploiting monopoly to obtain the evidence with which to club non-licensees into submission, is it any wonder that practically the whole mining fraternity has been aroused to that spirit of self-defence which years ago found expression in the words, "Millions for defense, but not one cent for tribute"?

Production of Quicksilver

From April 1 to June 30, 1920, inclusive, 3685 flasks of quicksilver of 75 lb. was produced in the United States, according to F. L. Ransome, of the U. S. Geological Survey. This is 1214 flasks less than was produced in the first quarter of 1920 and 255 flasks less than was produced in the second quarter of 1919. Only 13 mines were reported as productive—8 in California, 1 in Nevada, 1 in Oregon, and 3 in Texas. California produced 2704 flasks, Texas 952 flasks, and Nevada and Oregon together 29 flasks. The average monthly price of quicksilver per flask in San Francisco for the quarter was \$100 in April, \$87 in May, and \$85 in June. The average price for the quarter was therefore about \$91 as compared with about \$86 for the first quarter. The chief cause of the decrease in production during the second quarter was the destruction by fire, on June 20, of the reduction plant of the New Idria mine, in California, and the consequent loss of quicksilver already reduced during the earlier part of that month. Because of this misfortune the production for the third quarter of 1920 will probably be still smaller than that for the second quarter. Reconstruction is in progress, and it is expected that the plant will be in partial operation in August or September of this year. Other causes that contributed to the decrease in production were a shortage of efficient labor and a reduction in the average grade of the ore. At a time when initiative in the quicksilver-mining industry is at a low ebb and the tendency is rather to abandon enterprises already begun than to embark on new ones it is of interest to note that the formerly productive Klau mine, in San Luis Obispo county, California, has been re-opened under the same management as the Carson mine, and that its 50-ton furnace has been put in repair.

LARGE DEPOSITS of iron ore are uncommon in the northern Rocky Mountains, so that considerable interest is attached to some deposits near Stanford, Montana. The deposits are lens-shaped bodies of rather pure hematite that form a belt along the contact of limestone and an intrusive porphyry. The belt has been traced seven miles, and although the length of the lenses is not accurately known, the widths range from 5 to 60 ft., and one lens is explored 125 ft. below the outcrop.

The New Air-Shaft of the Davis-Daly Copper Company

*Since the Colorado mine became one of the deep mines of the Butte district, that is, after the workings reached a depth exceeding 1900 ft., the problem of efficient ventilation has been difficult. This problem has been met in several ways with varying degrees of success during the past three years. The first step toward obtaining efficient ventilation of the lower workings of the mine was the installation of an electrically-driven fan on the 2500-ft. level. This fan produced a slight, but noticeable, change in the air of the mine. It was not entirely successful, however, because of the fact that the Colorado shaft had to be used to carry both the descending and the ascending currents of air. In other words, it was both the 'downcast' and the 'upcast' shaft. The two hoisting compartments were downcast, and the pump and chippy compartments were upcast. The air was drawn to the 2500-ft. level by the fan and circulated upward through the stopes and upper levels of the mine to the 1400-ft. level, and thence upward through the pump-compartment.

As the workings of the lower levels of the mine became more extensive this system of ventilation ceased to produce the desired effect. A new source of fresh air became a necessity, and it was decided to connect with the Belmont mine of the Anaconda Copper Mining Co. To make this connection, a cross-cut 1000 ft. long was driven east from the Colorado 2500-ft. station and a similar cross-cut, approximately the same length, was driven west from the 2800-ft. level of the Belmont mine; the two cross-cuts being connected by the Colorado-Belmont raise, 185 ft. in height. This connection was made at a cost of approximately \$60,000. The ventilation problem of the Colorado mine was once more solved, and an ample supply of fresh air was obtained from the Belmont connection. The effect of this new supply of air upon the atmospheric condition of the mine was gratifying. Stopes which were previously devoid of ventilation now had a good supply of fresh air coursing through them. Since the 'holing' of the Belmont raise, however, the mine gradually grew until this source of supply was no longer adequate. The question now arose: What shall be the next step toward efficient ventilation and a new source of fresh air? It was then decided that the Colorado mine should have its own downcast and upcast shafts, and thus an adequate, efficient, and flexible ventilation system. At the present time a new shaft has been started which, when completed, will extend from the surface to the 1700-ft. level, a distance of 1800 ft. The shaft is to be octagonal in shape, six feet six inches in diameter inside of timbers, and timbered with solid cribbing. The shaft is now being raised for nine separate places; cross-cuts have been run and connecting raises are now being driven. A No. 14 centrifugal fan will be installed at the collar of this new air-shaft. The Colorado shaft will be made downcast. The supply of fresh air traveling downward through it will return through the new air-shaft.

*From the 'Bornite Sentinel'.

American Operations of the Consolidated Gold Fields of South Africa

In the recent annual report of the Consolidated Gold Fields of South Africa, Limited, an important holding and promoting corporation in London, we find the following account of its activities in this country:

AMERICAN TRONA CORPORATION

The results of operations for the year 1919 were as follows:

Gross earnings	\$1,116,949.09
Potash and borax salts in stock on December 31, 1919, at cost	180,572.58
	<hr/>
	\$1,297,521.67
Operating expenses (excluding depreciation and interest charges)	1,532,153.49
	<hr/>
Operating loss	\$ 234,631.82

For the eight months ending August 31, 1920, during which time the new management has been in charge of operations, the results have been as follows:

Gross earnings	\$1,187,296.96
Potash and borax salts in stock on August 31, 1920, at cost	138,480.55
	<hr/>
	\$1,325,777.51
Operating expenses (excluding depreciation and interest charges)	1,012,137.67
	<hr/>
Operating profit	\$ 313,639.84

There was produced 13,296 tons of potash and borax during the year 1919, and 8511 tons during the first eight months of this year. The potash and borax produced have gradually been brought up to a higher and superior grade and are now readily marketable.

Satisfactory progress is being made toward the solution of the various chemical and mechanical problems. The plant has been considerably simplified and the amount of labor appreciably reduced. Further improvements contemplated should result in increased production and reduced costs.

The plant is being adapted to new operating conditions to as great an extent as possible and the changes required have so far involved comparatively little new capital expenditures, which latter have been paid out of income from operations.

California Trona Company during 1919 marketed 482 tons of crude trona and 777 tons common salt, and during the first eight months of 1920, 440 tons of crude trona and 3193 tons of common salt.

During 1919 the Trona railway, of which the American Trona Corporation owns the entire stock and bonds, showed an operating revenue of \$162,457 and operating expenses of \$96,054. Interest on bonds and miscellaneous deductions from income amounted to \$35,718, leaving

\$30,685 net profit for the year. During the first eight months of 1920 the net operating profits were \$31,493.

SOUTH AMERICAN GOLD & PLATINUM COMPANY

Efforts of the management have been directed largely toward the equipment of the various properties and the operating results have not been representative of what shortly may be expected. Now that war-time conditions are being overcome and both labor and materials are in more plentiful supply, it is confidently anticipated that this work will proceed much more rapidly in the future than it has in the past.

During the year 1919 the operations of No. 1 dredge yielded 6349.2 oz. platinum and 972 oz. gold of an approximate value of \$700,000. This is a satisfactory recovery in comparison with the previous year's results in view of the fact that the dredge was closed down for extensive repairs during two months of last year. It is of interest to report that, despite a complete shut-down for repairs in January, the production for the first eight months of 1920 has shown a substantial increase over the same period of 1919.

Dredge No. 2 was completed and began digging on August 16 of this year. It is now digging its way out of the pond in which it was constructed, and toward the ground which it is intended to operate. This dredge has a capacity very much larger than No. 1 dredge. A third dredge, of even larger rated capacity than the No. 2, is now being fabricated in the United States, and it is expected that this will be erected in time to commence operations by the middle of next year.

This company is amply financed to carry out its equipment program, inasmuch as it now has in its treasury in excess of \$650,000 in cash and United States government securities, in addition to which there are considerable sums in the treasuries of its operating subsidiaries, and substantial payments have also been made on dredge No. 3.

YUBA CONSOLIDATED GOLD FIELDS

Dredging operations for the fiscal year ending February 28, 1920, are as follows:

		Per cu. yd.
Total returns	\$3,213,213	13.66c.
Expenses	1,567,665	6.67c.
	<hr/>	<hr/>
Profits	\$1,645,548	6.99c.

The 12 months ending February 28, 1920, have been the record year in point of operating output and the number of cubic yards dredged, but owing to the decrease in values the net profit is \$316,878 less than the previous year. There was much ground dredged during the year that yielded little, due to considerable channel dredging

in accordance with an agreement with the War Department.

For the four months ending June 30, 1920, the net operating profit was \$416,713. The average yield per cubic yard was 11.22c., with expenses averaging 6.16 cents.

MISSISSIPPI RIVER POWER COMPANY

The results of operations for the year 1919 were as follows:

Gross earnings	\$2,321,954.21
Operating expenses and taxes	522,629.71
Net earnings	\$1,799,324.50

The gross earnings increased \$108,562 as compared with the previous year, and notwithstanding the fact that taxes increased \$39,282, and a charge of \$53,842 was made for depreciation, the net earnings showed an increase of \$32,918. The decrease in operating expenses was due largely to very favorable river-flow conditions which made it unnecessary to buy any steam-relay during the year. It is interesting to note that 80% of the earnings of the company came from public-utility customers, three of them having made new high records for consumption, and initial service having been furnished during the year to several new customers.

For the six months ending June 30, 1920, the results of operations were as follows:

Gross earnings	\$1,282,569.42
Operating expenses and taxes	294,572.17
Net earnings	\$ 987,997.25

The adjustment of rates under the St. Louis contract referred to in last year's report gives the company additional revenue at the rate of \$277,777 per annum from August 1, 1919, to July 31, 1928, inclusive.

This company's power-station development, which spans the Mississippi river at Keokuk, Iowa, has a generating capacity of approximately 150,000 hp., with flow-age-land, dam, and station foundations for an ultimate capacity of approximately 200,000 hp. The company is furnishing at present 100,000 hp. to the city of St. Louis, neighboring cities, and adjacent territory.

SIERRA PACIFIC ELECTRIC COMPANY

The results of operations for the year 1919 were as follows:

Gross earnings	\$681,891.38
Operating expenses and taxes	379,752.18
Net earnings	\$302,139.20

The decrease in gross earnings of 5½% as compared with the previous year was due principally to the closing down of the copper mines and smelter in the Reno district on account of the unsatisfactory condition of the copper market which followed the close of the War. Prosperous conditions, however, prevailed in Reno, although the shortage of labor and prevailing high prices discouraged building. The electric-light and water business showed a small increase over the previous year, and in the gas business there was a gain of about 4.3% due

to increased rates. An increase in power-rates was secured, effective October 1, 1919, for the territory outside of Reno. The combined operating expenses show a slight increase over those of the previous year, due largely to an increase in the price of oil for gas manufacture, and taxes increased 31%.

For the six months ending June 30, 1920, the results of operations were as follows:

Gross earnings	\$388,043.97
Operating expenses and taxes	203,349.76
Net earnings	\$184,694.21

The gross earnings for these six months were \$76,056 more than for the same six months of 1919, operating expenses and taxes \$19,770 more, and the net earnings show an increase of \$56,286.

The company has recently closed contracts for the sale of additional power to the Southern Pacific Company for its shops at Sparks and to an affiliated company, the Pacific Fruit Express Co., for refrigerating plant. It is expected that the gross revenue from these contracts under which power will begin to be taken early in 1921 will amount to about \$35,000 per annum.

NORMAN OIL EXPLORATION SYNDICATE

This Syndicate was formed the early part of this year with the small capitalization of \$100,000, of which your company owns a 51% interest. The purpose of the syndicate is to purchase oil leases on good geological structure in the State of Oklahoma and adjoining States, with a view to selling these leases later at a profit. Considerable acreage has so far been acquired, the greater part of which has already appreciated in value. Consideration is being given at the present time to an extension of this business.

NEW BUSINESS

During the past year many mining propositions have been submitted to us and considered, but until recently the prices asked have been too high. There is every prospect that we shall in due time be able to acquire interests in new and profitable mining ventures.

IT IS REPORTED that Hilario Lazoya, recognized as the leader of mining in the Guanacevi mining district, has formed a syndicate with a capitalization of \$8,000,000 for the construction of a smelting plant in the centre of the Guanacevi district, one of the leading silver-producing sections of Durango, Mexico. According to official statistics there are over 300 mining properties in this vicinity which produce silver ore in paying quantities. The records of some of these mines show them to have produced extremely rich ore. Many of the old-time American mining men are returning to this district to resume operations. Señor Lazoya is a friend of them all. He is well known in El Paso and other border cities and one of the most prominent citizens of the State of Durango. He was at one time governor of the State and has often been offered responsible government positions in Mexico City but his mining interests would not permit of his absence.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

WAGES REDUCED TWENTY PER CENT.—PLACER MINES NEAR KINGMAN TO BE OPERATED.

BISBEE.—A reduction of wages, averaging 20%, by all the mining companies of Arizona, including the Bisbee, Verde, Globe, and Miami districts, has been announced. The copper companies of the Globe-Miami district have posted notices on their properties announcing a flat reduction of wages of one dollar per shift in all departments, effective January 21, 1921. The adjusted wage for miners will be \$5.15, which, according to the scale agreement adopted prior to the War, is the wage based on 22c. per pound as the selling price of copper. Employees of the following companies will be subject to the reduction: Inspiration Consolidated Copper Co., Miami Copper Co., Arizona Commercial Co., and the Iron Cap Copper Co. No further reduction of working forces is anticipated by the larger producing companies of the Globe-Miami district. A meeting of the Arizona chapter of the American Mining Congress was held on December 6 at Phoenix, and was attended by presidents, general managers, or other chief officials of the principal mining companies operating in the State. It is understood that the question of wages was taken up at this meeting, and that an agreement with regard to the reduction was reached by the various companies represented. No labor trouble is anticipated as a result of reductions, as such action is generally expected by miners throughout the State.

Directors of the Calumet & Arizona Mining Co. arrived at Bisbee on December 8, on a tour of inspection of the company's properties at Bisbee, Douglas, Ajo, Jerome, and Lordsburg, New Mexico. Included in the party were Charles Briggs, president; Thomas Hoatson and G. R. Campbell, of Calumet, Michigan; George A. Newett, of Ishpeming, Michigan; T. F. Cole, of New York; T. H. Collins, of Princeton, Massachusetts; and W. B. Mershon, of Saginaw, Michigan. George A. Newett, who is also the editor of the 'Iron Ore', and one of the best informed men in the country on copper, expressed the opinion that it will not be as long as many think before the copper market shows signs of revival. In this connection he spoke of the possibilities of a great advertising campaign to bring before the consumer the many possibilities and advantages in the use of copper in certain products where other metals are now used. He declared that advertising is a field that has been much neglected by producers of copper.

GOLDFIELD.—A new record in shaft-sinking is aimed at by Willis Lawrence, superintendent of the George Young mine. The work will be done by a crew of five men, all members of the team that beat the world's record last February at the Van Dyke Copper Co.'s property at Miami, where they sank a shaft to a depth of 308 ft. in 31 working days. This beat the record that was established by a crew in the mines at Johannesburg, South Africa, where 279 ft. was made in 31 days. Work on the shaft at the George Young mine has started.

JEROME.—Discovery is reported of a whole mountain of mineral paint, on the Verde river, about 16 miles by air-line north of Jerome. Claims on the property have been staked, and the locators expect to place their proposition before paint manufacturers in the near future. The best quality of paint lies in two veins, one four feet wide and the other 14 in., but it appears that the entire hill is a paint mine and a steam-shovel proposition. At the annual stockholders meeting of the Shea Copper Co., all the old directors were re-elected without opposition. These are: D. J. Shea, R. E. Moore, O. G. Engelder, John Goodwin, all of Jerome, and E. G. Bush, of Tucson. Of 838,542 shares of stock outstanding, 635,152 were represented; 428,946 in person, and 206,206 by proxy.

KINGMAN.—It is said that good orebodies have been opened on the tunnel-level of the Dean mine. About 40 men are now being employed in carrying on development and installing new machinery. Rapid progress is being made in the preparations for sluicing at the Harris placers, 80 miles north-west of Kingman in Jumbo wash in the Black Canyon district. A large pumping-plant is being installed by Shaw & Harris at the river from which water for sluicing is to be obtained. These placers have been known for many years; they are found in a district in which there are a number of important gold veins, among which is the Jumbo. J. W. Prisk, owner of the Home Pastime mine in Mineral Park, has shipped a carload of high-grade gold-silver ore. Development work is to be commenced immediately on the 300-ft. level. Due to faulting, the former owners failed to pick up the ore on this level. Henry Lovin has been appointed receiver by the Hackberry Consolidated Mines Co. by Judge Bollinger of the Superior Court upon the application by the creditors for such procedure. A lease on the mine has also been given to William Neagle on a royalty basis. The receivership resulted from the failure of various interests to agree upon a consolidation scheme and to finance further work. It is reported that a large

tonnage of ore has been developed in the upper levels of the mine. T. Hill and M. Kari have taken a bond and lease on the Rawhide mine close to Bill Williams fork in the Owen's mining district. This property is reported to be one of the oldest mines in the State having been worked in the 'sixties. Thousands of dollars of high-grade copper ore has been taken out by lessees in the past.

COLORADO

REDUCED FREIGHT-RATE ON LOW-GRADE ORE FROM IDAHO SPRINGS IS OBTAINED.—URANIUM DISCOVERY APPEARS IMPORTANT.

ASPEN.—Supplies have been hauled into the Leadville mine, Varney Tunnel, and Camp Yeckel of the Aspen Silver-Lead company on Porphyry mountain, and operation will be maintained during the winter. The Leadville and Varney Tunnel are shipping ore—a heavy zinc carbonate—by motor-truck for consignment to the A. S. & R. smelter at Pueblo. The high-grade carries 60% zinc, but the bulk of the ore runs 30% zinc, 25 to 35% lead, and 30 to 40 oz. silver per ton. The Aspen Silver-Lead company is drifting from the Deane tunnel on the main Silver fault, and will shortly intersect the East & West fault where a rich orebody is indicated by correlation of geological data.

RICO.—The Mt. Pleasant Mining Co. has sent supplies to the Smuggler-Almont property at Denton and will continue developing orebodies already exposed and exploration of new territory during the winter. The mine was a good producer in the past but of late years has not been actively operated.

ROLLINSVILLE.—Trinidad capitalists have become interested in the Moody group near the old town of Gilpin in the Central district. A one-half interest has been purchased in the Baxter, Gold Crown, and Swear-Off claims, Moody retaining the remaining half. Gold-silver ore running as high as \$240 per ton has been mined from shallow workings and a tunnel to undercut the vein at depth is projected. The Moody group is about one-half mile south-east of the Perigo, now closed through litigation but with a record of production exceeding \$3,000,000.

CENTRAL CITY.—The discovery of uranium ore in the Gold Rock mine in the Russell district is proving-up with development and the streak according to late reports measures 8 in. of solid ore, stripped for more than 20 ft. Tests have shown as high as 50% uranium but a conservative estimate places value of the ore at close to \$10,000 per ton. The ore is closely sorted and sacked and the lessees McCampbell and McLain of Colorado Springs will shortly make a shipment to a Denver plant when the actual value will be determined. The same operators recently shipped a five-ton lot to the smelter that returned 20 oz. gold in addition to some silver and copper. A carload shipment of second-grade ore netted \$120 per ton. The Rialto mine is being unwatered by a syndicate of Denver and Wyoming operators. The shaft is 700 ft. deep and the water has been lowered 200 ft. The prop-

erty, when operated some 30 years ago, produced good ore.

The Rara Avis has been drained by St. Louis people and production from this mine in Eureka gulch will shortly be resumed. Samples taken have shown as high as 25 oz. silver, 1.90 oz. gold, and 48% lead. A heavy sulphide ore assaying as high as 25 oz. gold, 36 oz. silver, and 10% lead has been opened by contractors sinking on the Claire Marie. The property is well equipped with machinery and is being operated by Boston capital. Sulphide ore has been opened up in the Barrick tunnel of the Saco de Oro company at Apex and development work on the vein is planned.

IDAHO SPRINGS.—Close to 50 tons daily of mill-ore is handled at the concentrating plant of the Gem company and is resulting in about six cars monthly of concentrate of a good grade. The company is doing extensive development and has opened an ore-shoot at the 6th level of the Freighter's Friend 100 ft. in length. The ore is of good milling-grade. The Idaho Springs Chamber of Commerce has successfully negotiated a low rate of 75c. per ton on ore shipments valued at less than \$30 per ton. Most of the ore shipped from the district comes under this classification.

LEADVILLE.—The Blaine shaft has been sunk to the 350-ft. level, a station cut and drift started to a point under the orebody opened in levels above. The mine continues production of 50 tons daily and with the new level opened production will be doubled. The ore is shipped to the A. V. smelter. Lessees of the Emma & Mabel placer adjoining the Gold Leaf are extending the tunnel to the quartzite-lime contact, where they are confident an orebody will be found.

Zinc-oxide ore has been opened on the first level of the Fanny Rawlins. The vein on the third level carries only silver, although the mine is in the gold belt. From the second, third, and fourth levels lessees are shipping gold, silver, and copper ore, the highest grade from the deepest level averaging \$50 per ton, at the rate of 50 tons weekly. One car weekly of the zinc oxide is shipped to the Western Oxide smelter and the production will shortly be increased.

Lessees at the Chrysolite mine, on Fryer hill, are shipping lead-silver ore running 40% lead with about 11 oz. silver per ton. Other Fryer Hill mines active and producing are the Climax, Dunkin, Amy, May Queen, Little Chief, Ponsardin, Little Pittsburg, Robert E. Lee, and Venture.

TELLURIDE.—Shipments of concentrate during November totaled 102 cars and were distributed as follows: Tomboy 50 cars; Smuggler-Union 40; and Liberty Bell 12. The Vanadium Corporation of America has shut-down, discharged all employees, and sold or removed all stores. Vanadium is practically deserted as about 100 men formerly on the company payroll have or will seek employment elsewhere. The Matterhorn mill of the Valley View Leasing & Mining Co. is reported treating successfully in excess of 100 tons of ore from the San Bernardo property.

MICHIGAN

CALUMET & HECLA SMELTER WILL PRODUCE 1,000,000 LB. PER MONTH.—DEVELOPMENT AT ARCADIAN CON.

HOUGHTON.—Copper Range Consolidated is now on a wage and salary basis that will permit it to keep its mines in operation, although there is little hope of making a profit on the present price of copper. During the War, Copper Range, as well as other mining companies in this district, was compelled to bid high for unskilled labor until the quest for workers reached a point where the pay of an unskilled man was about on a level with that of the skilled worker. In the readjustment of wage-scales this situation has been taken into account and the experienced skilled man is the one who suffers the least. The biggest cut has been in the wage of the unskilled

while the remainder of the force is employed full time.

Quincy has taken on a few former Calumet miners, but its force is far from normal, and production for 1920 will be considerably below that of 1919. Costs, on the other hand, should compare favorably with those of last year. The re-grinding equipment at the mills was started during the summer, making for an additional recovery of copper. The full benefit of the improvements at the smelter will not be reflected to a great extent this year, but operating at capacity there will be a material saving in smelting and refining costs.

Mohawk's daily tonnage has been increased to practically 2200 tons of 'rock' per day. It is expected that this will be up to 2400 by the middle of the month. In No. 1 shaft, just re-opened, a force of miners is employed

STEAM-STAMP IN A MICHIGAN STAMP-MILL

worker, the Copper Range reduction in some cases being 22%. The average reduction by Copper Range, however, is 17%. Every effort has been made to relieve the burden of the married man as much as possible. In selling coal to him for \$7 per ton and returning \$2 to him if he has already paid \$9 for it, the company takes an actual loss of \$4 per ton, the fuel costing \$11. The coal item alone represents a loss of \$16,000. In reducing the rent of houses 50c. per room per month, making the rate \$1, the company also takes a considerable loss. There will be no curtailment of forces at Champion, Trimountain, or Baltic or at mills or smelter. A few married men from other mines have been given employment at Champion and Trimountain.

At the Calumet & Hecla smelters six furnaces have suspended and two or three more will draw their fires. This will leave in operation 12 furnaces, including two of large type, the capacity of which is 1,000,000 lb. per month. About 150 smelter employees have been let out,

in drifting and stoping from the 23rd to the 25th levels. This increases the operating shafts to four, No. 1, 4, 5, and 6, with the largest tonnage coming from No. 4 and 6. No. 1 will contribute materially to production, once the force becomes normal, and it is expected that the tonnage from this shaft will be as great as that from No. 6. In No. 4, 5, and 6 a full program of drifting, sinking, and stoping is under way.

Arcadian Consolidated is down 765 ft. in its New Baltic shaft. It is sinking 75 to 80 ft. per month and at the depth of 940 ft. connection will be made with the 900-ft. level of the New Arcadian shaft, 3500 ft. distant. The shaft is being timbered, piped, laddered, and railed as sinking proceeds, and the objective, it is expected, will be reached about March 1. New Arcadian at 900 ft. has a drift in 700 ft. toward the New Baltic and drifting will proceed from both shafts when New Baltic is bottomed at 940 ft. One station has been cut in the New Baltic shaft at the 600-ft. level and the next one will be put in

at a depth of 790 ft. It also is planned to connect the two shafts at that depth, which in the New Arcadian is equivalent to 750 ft. The lode was tapped in New Baltic at 250, 400, 500, and 600 ft. and from 600 down the shaft has been in the vein. According to the management, the lode, which is known as the New Arcadian amygdaloid, is uniformly mineralized, with considerable small 'mass' and 'barrel' copper as well. The showing in the New Arcadian shaft is considered equally encouraging. Only a small amount of drifting has been done at points of contact with the lode in both shafts, but enough to demonstrate the uniformity of the mineralization and commercial value of the vein as far as it has been opened. With the connections at the 900 and 750-ft. levels, a large area will be available for mining. The Franklin mill, which is convenient and adequate, probably will be used when sufficient openings are made to warrant actual production.

Mayflower's cross-cuts, east, from the south drift, have stopped after finding the hanging-wall trap and the principal operation now in this section of the 1700-ft. level is a continuation of the drift. At present it is breasted in spotty trap matter. In the raise in the north cross-cut, now about 50 ft. high, the conglomerate vein still appears, with bunches of copper, yet not in commercial quantities, exposed from time to time.

NEVADA

PRODUCTION AT THE WARD MINE IS INCREASED.—GOLDFIELD CONSOLIDATED WILL LEASE BLOCKS AFTER JANUARY 1.

ELY.—Shipments through East Ely from the Ward mine, 12 miles south of Ely, have been increased to 1500 tons monthly and in a short time will be increased again to 3000 tons monthly, according to S. B. Elbert, manager. The company is using five 7½-ton motor-trucks in hauling. Regular shipments to Utah smelters have been made for nearly four years. The decision to increase the output is said to have been due to the recent decision of the Interstate Commerce Commission giving the Nevada Northern railroad permission to reduce rates on low-grade ore.

TAYLOR.—Four suits, two for a total of \$2832 and the others for smaller sums, have been filed against the Wyoming Mining & Milling Co., which in 1918 took an option on the old Argus mine for \$90,000. The \$2800 suits were brought by the Ely National Bank and they are actions to recover on promissory notes. The Wyoming company has built a mill and has done much development work. There has been paid \$27,000 on the purchase price of \$90,000. The filing of the suits followed the failure of the company to make a \$30,000 payment on December 1.

MONTEZUMA.—The Harmill company has erected a hoist, head-frame, and five buildings at the 100-ft. shaft sunk by Moon and Whitaker, from whom the company bought the claims. The shaft is to be sunk to 500 ft. and the first lateral work below the 100-ft. level will be done at 150 to 200 ft. from the surface, or when the junction

is reached with the No. 4 vein, in which the shaft is sunk, and vein No. 1, which is thought to dip into No. 4. When the Harmill bought the claims silver-lead ore 3 to 4 ft. wide and assaying \$90 to \$125 for this width had been opened on the 50 and 100-ft. levels and since then this ore has been found for a length of 35 ft. without reaching the end of the shoot. There are seven veins in the eight claims and three of these can be explored near the shaft. It is reported that \$75,000 worth of ore was produced in the early days from vein No. 1 and stopes in the vein indicate that this figure probably is correct. The veins are replacements of limestone. The ore contains lead sulphide and carbonate, copper, and silver, the last making one-tenth of the value of the lead. The ore also contains quartz, calcite, and fluorite. The shipping point is Klondyke on the Tonopah & Goldfield railroad, 15 miles distant.

TONOPAH.—Bullion shipments from the district in the last half of November were heavier than usual, reaching a total of 222,657 oz., exclusive of the Tonopah Mining. The Belmont shipped 99,407 oz.; Tonopah Ex., 51,905; West End, 50,700; and MacNamara, 20,645.

GOLDFIELD.—Sampling of the Meuli lease workings of the Lone Star that were taken over by the company after the richest part of the shoot had been mined shows that there is \$30 to \$40 ore in the drift faces on the 20 and 60-ft. levels and in a stope from the 60-ft. level. The north drift on the 250-ft. level of the Nelligan shaft has been driven 250 of 280 ft. necessary to reach under the lease workings. The south drift on the 150-ft. level also is being driven for prospecting under the Meuli block. A. H. Lawry, general superintendent for the Consolidated, has announced the following royalties on net returns to be paid by lessees: 10% on ore of a gross value of not more than \$20; 15% on \$20 to \$40 ore, and 20% on ore assaying more than \$40. The mines will be opened for lessees about January 1. Ore will be shipped to the Millers plant of the Tonopah Mining and the Tonopah & Goldfield railroad has granted reduced rates between Goldfield and Millers. The Deep Mines has resumed work. The Grandma has added a second shift of miners in sinking the shaft, which is now 910 ft. deep. The flow of water is much less than heretofore and from now on good progress should be made, according to J. K. Turner, general superintendent.

GOODSPRINGS.—It is reported that the Yellow Pine mine and mill are to be closed because of the low price of lead and zinc. The production of the mine is 1600 tons monthly and the company has paid more than \$3,000,000 in dividends.

STONEWALL.—The Yellow Tiger is hauling supplies from Goldfield and will resume driving of the Sterlag tunnel.

ROCHESTER.—The Nevada Packard will not be reopened until spring, according to Herman Davis, receiver for the company. The mine was closed last August when the electric power failed at Rochester and surrounding districts because of low water in the Lahontan reservoir

at Fallon. High costs, shortage of labor, and inadequate power are given by the receiver as the reasons for his decision not to resume work during the winter.

QUARTZ MOUNTAIN.—The Goldfield Quartz Mountain Mining Corporation is preparing to start work at Quartz Mountain, a gold district 12 miles east of Goldfield. The starting of work by this company is regarded as of importance because of numerous favorable opinions that have been expressed regarding the claims and because of the highly favorable report made by Corrin Barnes, a Goldfield engineer. No work has been done in the vein except on the surface, where the assays secured by Mr. Barnes were as follows: 8 ft. width, \$8; 18 ft., \$17; 24 ft., \$5.20. The value of the ore is entirely in gold in the form of crystalline flakes in quartz. A tunnel now 160 ft. long will be continued an additional 65 ft. to cut the vein. The company has bought a 25-hp. gasoline-engine and an air-compressor.

PIOCHE.—Ore shipments for the week ending December 3 show a large increase over those made during the preceding week. The Prince Consolidated shipped 1865 tons; Virginia-Louise, 950; Combined Metals, 305; Bristol Silver Mines, 240; Black Metals, 50; Hamburg Mines, 45; Fairview lease, 40, making a grand total of 3495 tons. Additional men have been employed at the milling plant of the Southern Nevada Mining Co., and it is expected by early spring it will be treating ores. The mill was designed by the late Oscar A. Knox. A contract has been let for additional buildings to be constructed near the milling plant.

UTAH

VALUATION OF NON-METALLIC MINERAL PROPERTIES IN UTAH.—REPORT OF BINGHAM MINES CO.

SALT LAKE CITY.—Non-metalliferous mining deposits in Utah have an assessed valuation, for taxation purposes, of \$22,686,748 for the current year, which is practically double the assessed valuation for 1917. The coal lands of the State are assessed at \$19,091,647; asphalt deposits, \$1,062,764; alunite deposits, \$274,477; salt and potash deposits, \$644,447; cement deposits, \$1,372,755; phosphate deposits, \$186,195; lime quarries, \$31,943; sulphur deposits, \$22,530.

During the week ending December 4, the Murray plant of the Utah Ore Sampling Co. released 70 cars of ore from Utah mines, 4 from Nevada mines, and 1 from California, while at its Tintic plant, 42 cars of Utah ore were handled.

A patent has been granted to the Utah Salduro Co. for an area of 30,658 acres of land in the Great Salt Lake desert, title to which was established under placer-mining locations made prior to the date of the leasing law. The company paid an entry fee of \$76,645. This entry covered probably the largest area ever patented under one mineral application. The company extracts the potash salts from brine collected by means of an extensive system of dikes, ditches, and canals.

PARK CITY.—Ore shipments from this district for the week ending December 4 totaled 2105 tons, of which the

Judge allied companies shipped 865; Silver King Coalition, 596; Ontario, 506; Naildriver, 60; Keystone, 55. The Judge smelter shipped 25 tons of premium spelter. Installation of the new electrically operated compressor and hoist by the New Quincy company at the Little Bell property was completed on December 8, according to A. L. Thomas Sr., manager for the company. The New Quincy company has a five-year lease on the Little Bell shaft and equipment. Work of cleaning out the shaft has been started. Heretofore all work done in the New Quincy property was from either the Ontario drain-level or from the Daly-West company's 900-ft. level. Under

NEVADA

the new arrangement, ore will be taken out through the Daly-West or Ontario properties, and waste through the Little Bell shaft.

EUREKA.—During November the Tintic Standard Mining Co. shipped 181 cars of ore, approximately 9000 tons, which is the largest monthly output so far reported by the company. It is expected that December shipments will total 200 cars, and possibly 215 cars. The present output is excellent ore. E. J. Raddatz, president, announces that the new milling plant, with an initial capacity of 150 tons per day, will be ready for operation January 1. The company is earning substantial profits, in spite of the present market quotation of five cents per pound for lead.

During the week ending December 4, ore shipments

from this district were the heaviest of the year, a total of 199 carloads being shipped. Tintic Standard shipped 62 cars; Chief Consolidated, 40; Mammoth, 20; Dragon, 17; Eagle & Blue Bell, 15; Iron Blossom, 9; Victoria, 8; Iron King, 6; Grand Central, 6; Centennial Eureka, 6; Swansea, 4; Gemini, 3; Bullion Beck, 2; Alaska, 1.

At a meeting of the directors of the Eureka-Bullion Mining Co. on December 4, an assessment of one-half cent per share was levied, payable January 5, sales date January 26. The last 60 ft. of work on the 925-ft. level has cut a brecciated limestone, with stringers of quartz, some of which have been rich. One of the veins cut recently was followed several feet and opened up 18 in. of good ore. A north-south fault-fissure filled with sand carbonates and lead boulders has also been entered. One boulder, with an estimated weight of five tons, averaged 58 oz. silver, 54% lead, and \$2.40 in gold per ton. Another boulder averaged 107 oz. silver, 40% lead, and \$4.40 gold per ton.

At the North Standard property, the shaft has passed the 900-ft. level, according to John Manson, manager. An average of four feet per day is being accomplished. The bottom of the shaft is now in a white limestone, similar to that found in the Tintic Standard. The shaft will reach the 1000-ft. level before the close of the year.

GOLD HILL.—At the Western Utah Copper property, gratifying results are being obtained from the development under way on the 300-ft. level. At a distance of 300 ft. from the shaft, 25 ft. of ore, which contains an excess of iron, 5 oz. silver, and 5% lead, has been opened up for a distance of 150 ft. From 150 to 200 tons of low-grade ore is being shipped daily. Up to the present time no sulphide ore has been found. The company's engineers believe that the sulphide zone will not be entered until a point below the bed of the old lake is reached, which will be about the 1400-ft. level.

BINGHAM.—Operations during the current year by the Bingham Mines Co. and its subsidiary, the Eagle & Blue Bell Mining Co. at Eureka, Utah, have been successful and profitable, according to Imer Pett, general manager. During the first four months of the year, when high prices for silver and lead prevailed and the supply of labor was ample, the companies enjoyed large production and high earnings. The following six months were marked by an extreme shortage and inefficient supply of labor, which curtailed output. However, during November, with an adequate supply of labor and increased efficiency, production has been greatly increased. Development at the Eagle & Blue Bell indicates that the mine will have a long productive career. In the Bingham properties, recent work at depth demonstrates that the ore deposits are as large and their extraction as profitable as was found on the upper levels.

WISCONSIN

REVIEW FOR NOVEMBER.

The serious predicament of the zinc-mining industry of this region through the early autumn was further intensified during November, through declining markets,

inclement weather, and bad roads. The mines of the New Jersey Zinc Co., and those of the Steel & Tube Co. of America, have succeeded in maintaining full working crews, notwithstanding the reduction of wages for all classes of mine help. Shovelers' wages were reduced 15%. Millmen, hoistmen, workers on grizzlies, and other mine help came in for a cut of \$1 per day. More mine help, apparently, was obtainable in spite of these reductions, as shift-crews held to their jobs all month and the complaints heard relative to a scarcity of men vanished completely.

The offerings on zinc ore at the beginning of the month held firmly, on a base price of \$45 per ton, for high-grade refinery blende. This price was declared not satisfactory and furnished the principal reason for trimming miner's wages. A drop in the price was registered about the middle of the month, the base price receding to \$43.50 per ton for high-grade blende. In the third week of the month the official sources from which quotations have been obtainable made the disconcerting announcement that no official market figures would be given out. Following this proceeding the Wisconsin Zinc Co., operating a group of zinc mines in the Benton district, suspended operations at its large magnetic-separating plant at New Diggings.

Deliveries of zinc ore for November from mines to separating-plants, in the field, were made by districts as here shown:

District	Zinc, lb.
Benton	7,920,560
Livingston	6,166,800
Cuba City	1,885,840
Galena	1,414,960
Day Siding	842,400
Shullsburg	760,240
Hazel Green	663,120
Platteville	374,800
Highland	60,000
Total	20,088,720

Shipments of finished blende to smelters from refineries were made as follows:

Company	Lb.
National Zinc Separators	2,826,000
Mineral Point Zinc Co.	744,000
Block-House Mining Co.	234,000
Total	3,804,000

No concerted movement designed toward a complete shutting down of zinc producers was heard, although reports were frequent that certain mines would suspend production and discharge working forces. No single instances were recorded to indicate that such a course was intended, and all active producers continued mining and milling.

Lead ore was in poor demand all month. A sharp decline in offerings came about the middle of the month, the price receding from \$65 per ton, 80% metal content, to \$55 per ton. Producers refrained from consulting the market, with the result that only 45 tons was marketed for the entire month, this negligible quantity

going to the Federal Lead Co. Production was fair and with ore long held in bin brought the reserve at the close of November to more than 1000 tons.

BRITISH COLUMBIA

THE PRESENT STATUS OF THE COPPER-MINING INDUSTRY.

VICTORIA.—The slump in the price of copper has hit the mining industry of this Province badly. Two weeks ago cessation of production at the Britannia mine was reported; recently the Granby Consolidated M. S. & P. Co. has laid off 400 men. This means, of course, a curtailment of production, and at a time when money is needed to meet interest on bond issues and taxes. The Granby company has outstanding at the present time two bond issues, totaling \$4,003,300, upon which the annual interest amounts to \$290,198. These bond issues were made necessary mainly to pay for the purchase and equipment of the Cassidy colliery, the company's title to which is being disputed at the present time by the Esquimalt & Nanaimo Railway Co., and the coke-ovens, at Anyox. From a metallurgical point the colliery has not been an unmixed success. The coal gives a high-ash coke, necessitating additional fluxes in the blast-furnace. At the present time the colliery is turning out upward of 20,000 tons of coal per month, a large proportion of which is being sold in the open market, and, with coal at present price, should bring a good return, but unfortunately for the Granby company this rate of output cannot be continued for long, as the court limited the total output to 100,000 tons, pending the result of the appeal. During the last fiscal year, ended June 30, the Granby company produced 23,127,847 lb. copper, 938,292 oz. silver, and 14,616 oz. gold; the bulk of the silver, however, came from the Dolly Varden ore, and 95% of the proceeds from it had to be paid to that company. During the second half of this year up to the present time the rate of output has been increased, the September and October output being close to 2,300,000 lb. each. It is claimed that the Granby company can produce copper for about 11 cents per pound, but this does not include payment of interest on bonded indebtedness or taxes, and these two items must add at least another three cents, bringing the total cost so close to the present market price of the metal that it is evident there is little, if any, profit in its production. The only other copper producer of importance is the Canada Copper Corporation. This concern has again reorganized, the second time within a few months, and this time has obtained a Dominion government charter, authorizing it to take over the existing properties as a going concern.

The authorized capital is \$10,000,000; the company's head office has been moved to Toronto. The plant was started in the latter part of October, but evidently no effort is being made to bring it up to full capacity with the price of copper where it now stands. The plant is treating 800 tons daily and producing 50 tons of concentrate. It is too early as yet to say whether this is being done at a profit, but considering the grade of ore that is being treated, the railroad haul to Trail, and the smelting

charges, it seems doubtful. Considering the ore-reserve is only 12,000,000 tons of about 2% ore, the capitalization seems excessive. The only other producer of copper is the Consolidated Mining & Smelting Co., which owns considerable copper areas on Vancouver Island as well as its gold-copper properties at Rossland. The values in the latter ore are in the gold rather than in the copper. During the unsatisfactory condition of the copper market since the Armistice the company has confined its copper operations to the development of the mines, and concentrated its energies on the more profitable enterprise of producing zinc; lead and silver coming largely as a by-product to the operation.

KASLO.—There is a revival of mining at Slocan, the richest silver-lead district in British Columbia. For months all the large producers have been closed down, with the exception of the Silversmith Mines, Ltd. (old Slocan Star), because of the refusal of the operators to

PART OF CHIHUAHUA AND SONORA

meet the demands of the men with respect to wages, accommodations, etc. They regarded the requirements of their employees, as expressed through an organization known as the 'One Big Union', as extravagant, and refused to take them seriously. A strike was called. There is no doubt that it was effective, for the mines were forced to inactivity. When the strike was first declared work was plentiful, as the lumber camps were able to absorb practically all able-bodied men who wanted employment. These camps now, in many instances, are closed down. There also is an influx of labor from the prairie provinces. The mines, therefore, are well provided with men and the old-established properties again are being put on a producing basis. The Noble Five mine at Cody has taken on a crew of between 65 and 70 men; the McAllister has obtained all the men required to carry on work planned; the Rambler-Cariboo has a full crew; the Rosebery-Surprise Mining Co. has re-opened the Surprise mine at Sandon as well as the Bosun at New Denver. The concentrators of the Rambler-Cariboo and the Noble

Five are in operation. It seems, therefore, that the strike is definitely broken and that the output of this section of the Province from this date on will begin to climb.

NELSON.—At the International Mining Convention held at Nelson during the summer it was resolved that the Dominion government should be asked to make provision for the prospecting and mining of base minerals on Indian reservations in this Province. As a result of the joint action of the Federal and the Provincial governments it is permissible at present to mine the precious metals on such reservations. This privilege is considered of little value in British Columbia.

ONTARIO

SUNDRY COMPANIES PASS DIVIDENDS.

COBALT.—Low quotations for silver and a shortage of electric power has caused considerable curtailment of work in the district. The Mining Corporation has announced that the company will not disburse the regular 12½c. dividend for the current quarter. The McKinley-Darragh has also announced that the regular 3% dividend, formerly payable January 1, will not be paid. The Temiskaming Mining Co. has ceased operations until next spring, and is disposing of its stock of supplies. The Kerr Lake is considering the question of curtailing work somewhat, while other mines are hesitant as to future policy. Wages are now the highest in Cobalt's history, in spite of silver being quoted at about one-half the high figure reached last January. A surplus of men exists and it is considered likely these men may volunteer to work at lower pay in order to induce the mining companies to continue operation. The Nipissing and the O'Brien are still able to produce silver at a cost of under 50c. per ounce.

A station is being cut at the 385-ft. level of the Chambers-Ferland mine preparatory to sinking a winze through the layer of slate to the underlying conglomerate. The high silver content of the stringers in the slate are believed to indicate the presence of a high-grade vein in the conglomerate. Sinking operations are under way on the Regent property, in the Elk Lake district. The shaft is down 35 ft. and silver occurs in a narrow vein all the way down. A small mill-test run of ore is being made this week.

KIRKLAND LAKE.—With the completion of the new mill of the Wright-Hargreaves, which will be finished at the end of the year, an important producer will be added to the list in the district. The Wright-Hargreaves property, about three-quarters of a mile in length on the main belt of mineralization, lies between the Lake Shore which has an annual production of over \$500,000, and the Tough-Oakes which, before it became involved in litigation, yielded nearly \$750,000 annually. The opening of the mill will depend entirely on the ability to obtain power. The Lake Shore has been able to keep its tonnage up to normal by the use of an auxiliary steam-plant. At the Ontario-Kirkland a good orebody is being opened up

on the 450-ft. level, the vein improving with development. Ore is being mined that is soft and easily milled.

WEST SHINING TREE.—The main vein on the Herrick has been traced for 1000 ft. Diamond-drilling has proved up the orebody to a depth of 800 ft., at which point the vein was 20 ft. wide with an average gold content of \$15 per ton. A shaft has been put down to a depth of 108 ft., a cross-cut from which has cut the main vein, which is reported as being rich.

BOSTON CREEK.—At the Miller Independence, A. G. Burrows and Percy E. Hopkins, Ontario government geologists, have been making a close examination of the formations on the lower levels. They devoted special attention to the faulting at the 500-ft. level which is probably a continuation of the fracture found in the 'D' shaft, where rich showings of gold tellurides were found.

MATACHEWAN.—A report by H. C. Cooke of the Canadian Department of Mines on the Matatchewan gold district noted the occurrence of peridotite in considerable quantities. This formation is favorable for the presence of asbestos, as well as garnets, platinum, and diamonds. Asbestos is known to occur in the district and in the hope of finding it in commercial quantities English interests have engaged J. B. Tyrrell, mining engineer of Toronto, to examine the deposits. The peridotites of Matatchewan are stated to be similar to those of the diamond fields of South Africa, which are also associated with garnets, magnetite, and limonite, so that a close exploration may possibly lead to important discoveries.

MEXICO

SITUATION IN CHIHUAHUA.

CHIHUAHUA.—Mining companies in Mexico are beginning to feel the effects of the fall in the price of silver, copper, and zinc. The depressing effects of a drop in prices came just at a time when a big revival of mining operations was beginning to be manifest. While the larger companies will continue to mine ore there are many smaller concerns that are dependent upon immediate shipments to continue development work which will have to shut-down soon. The Government has signified its intention of affording all possible relief to the mine-owners in the present situation. Taxes on low-grade ores have been materially reduced in order that mines of this character may continue operations. The fuel situation is also working a hardship upon the mines and smelters. The protracted strike of the coal miners and coke burners in the State of Coahuila has caused a severe shortage of fuel in some of the mining districts. An exception to this rule, so far as the working of the mines is concerned, is in the districts where electric power is available. In the Guanajuato district, where the mines and mills have for several years been supplied with electric power, these industries are flourishing. The districts in the State of Chihuahua, which obtain their electric power from the great hydro-electric plant of the Mexico Northern Power Co. at Boquillas on the Conchos river, also are suffering no ill effects of the fuel shortage.

THE MINING SUMMARY

ARIZONA

Miami.—Drilling has commenced on the Warrior Copper Co.'s ground in Lost gulch north of the Globe-Miami Copper Co.'s property. One diamond-drill has been installed. Other drills have been arranged for and will be placed as soon as drill No. 1 is well under way.

Prescott.—The Lucky Strike Mining Co., which was incorporated in August of this year and which acquired the Lucky Strike mine and 16 claims in the Hassayampa district, is pushing development work rapidly. Buildings have been completed and the cross-cut adit is in about 80 ft., two shifts of men being employed in this work. The surface shows ore that assays well in gold and silver. This ore, it is expected, will be cut by the tunnel at a depth of 150 to 250 ft. Plans are now being made for the construction of a 50-ton mill to be erected in the spring. Ore running as high as \$30 per ton is reported to have been opened by recent work on the Queen claim.—The Philadelphia Mining Co. has taken over the War Eagle-Gladiator property at Crown King on a five year lease. A cross-cut from the Philadelphia mine, which is adjacent to the acquired property, is to be run to the Gladiator vein. The ore is gold-silver-copper.—The Arizona Standard Copper mine, 14 miles north-east of Prescott, is hauling machinery for the 125-ton leaching plant. The crushing plant has been designed to crush double this tonnage. It is claimed that there is a large tonnage of 3 to 7% oxidized copper ore available. T. J. Carrigan is general manager.—Ore assaying over \$22 per ton in gold and silver has been opened at the Black Horse mine of the Peak Silver Mining Co. in the Senator district. A new shaft which was started a month ago 600 ft. to the north of the old shaft, has opened a four-foot vein containing high-grade shipping ore.

CALIFORNIA

Alpine County.—The gold-quartz mill used at the Hercules mine at Loope is being dismantled and the materials shipped to Reno. This property is owned by the Moffat-Humphrey Co., which operated the mine and mill for a time, but later decided to abandon plans for its development.—The Curtz mine is being re-opened and the old workings cleared out by the new owners, E. Farrell and associates of San Francisco. It is stated that this work is preliminary to development next season when a large crew of miners will be employed.

Nevada County.—A complete fire-fighting system has been installed at the Idaho-Maryland mine, and the first fire-drill has been held. The system makes it possible to use ten streams of water at one time, and by the aid of powerful monitors the entire plant can be swept. This mine is under the pipe-line which conveys water to the Empire and North Star mines and has a strong water-pressure.—The stamp-mill of the Idaho-Maryland has been started up and ore from the old Eureka mine, worked out and closed more than 40 years ago, is being reduced. The ore is being mined by lessees and is of good grade. The present operations are between the 300 and 400-ft. levels of the old mine, that section having been re-opened and explored through the Idaho-Maryland shaft. It is stated that no large bodies of ore have been discovered so far. The work of unwatering the

canyon shaft in the Idaho-Maryland mine continues, the water-level now being at the 1300-ft. station. It is understood that while no extensive explorations have yet been found practicable, a shoot of ore indicated by the old maps on the 1000-ft. level has been found and appears highly promising.

Ubehebe.—A representative of the United States Smelting & Refining Co. has agreed to treat ore from the Arrowhead Rico mine free of charge and to pay a premium to be agreed upon later, according to Sol Camp, manager for the Rico. The ore is now 9 ft. wide and it is being broken and sacked for shipment over this width. More than 100 tons of ore assaying \$100 has been broken at a depth of 80 ft., much of it containing as high as 60% lead.

IDAHO

Coeur d'Alene.—Three new claims have been taken over by the Gold Hunter company, giving the company consider-

ENTRANCE TO KELLOGG ADIT

able additional ground that will be of much value. The properties are secured from the Greenough estate. The claims are the Clear Grit, the Paymaster, and the Lost Wonder.—Activity prevails throughout the Mullan district. The Morning mine is opening its old upper workings. Good work is being done by the American Commander, which is now working a double shift. It is driving a tunnel under the shaft toward the Gold Hunter lines.—The first car of ore from the Yankee Boy and Yankee Girl mines, on Big creek, has been shipped and will be followed by a second in a few days. It is gray copper and assays 100 oz. per ton in silver. These properties were taken over recently by the Sunshine Mining Co., organized in Spokane by E. C. Tousley, mining engineer. W. F. Newton is manager at the property.—John Stout, who owns a property 24 miles above Prichard on the north fork of the Coeur d'Alene river, will

attempt to bring out by boat enough ore to make a car-shipment. His boat will hold 12 to 15 tons. The ore is a copper sulphate assaying 30% copper.

Forty-five tons of ore, the first shipment by lessees of the Western Union mine, gave a gross return of \$5151 and a net return of \$3716. It went to the Bunker Hill smelter.

MONTANA

Butte.—The North Butte Mining Co. has announced a curtailment of its production by about one-third. Some 450 men were laid off and it is expected to bring the production to between 400,000 and 500,000 lb. per month. The men retained are all married; they will be placed on development work.—Howard Martin, who is leasing the Hibernia from the Davis-Daly Co., reports pay ore in sight and intends to continue producing lead-zinc and silver ore.—The Colorado, owned and operated by the Davis-Daly Co., while having practically discontinued development work, is still keeping two shifts on the 'air-shaft' which is being driven from the 1700-ft. level to the surface.—The closing of the Leonard, one of the largest producers of the A. C. M., has been reported. This means the laying off of around 400 men.—The Timber-Butte mill is also shut-down.

Cedar Creek.—The old Cedar Creek placer diggings, located about 18 miles from Iron Mountain, produced more than \$40,000 in the season just closed. The deposits have been worked every year for the last 40 years, and during that period have produced many thousands of dollars. The claims are owned and worked by the Lacasse brothers of Missoula who are recovering the gold by ground sluicing.

Clancy.—Sinking operations are progressing at the Little Nell mine.—At the Pay-Streak mine near the King Solomon group, sinking is also being done and it is announced that the Free Coinage mine of the Amalgamated Silver is to sink further at once.—At the Mammoth mine, new equipment is being installed.

Cooke City.—The Republic, Glengarry, and Irma mines are producing some good ore. It is intended to continue operations throughout the winter; the ore is being hauled to the railroad at Gardiner, a distance of 57 miles, by large trucks.

Jardine.—The Jardine Mining Co. has closed its mine at Jardine, according to a report by H. C. Bacorn. About 40 men were employed.

NEVADA

Eureka.—A streak of galena has been cut in the face of the lower adit, about 850 ft. from the portal, in the Eureka-Nevada mine. When this adit is connected with the upper workings, which can probably be done by raising on ore from the lower to the upper level, this property will have made a good start for a permanent mine, and the haulage distance between the Eureka-Nevada and the railway at the lower end of the town will have been shortened.—The Eureka-Croesus Mining Co. shipped four cars of ore during the week ended December 4. From January 1 to November 30, inclusive, the total shipments of ore from the Eureka-Croesus mine averaged 1.44 oz. or \$29.71 gold per ton, besides the silver content.—At the Eureka-Holly the cutting of the station at the 500-ft. level has been finished, and the shaft is now down nearly 40 ft. below that level. The company has been shipping gold ore. The mill is expected to be ready to operate by about the middle of January.

MEXICO

Cananea.—The Cananea Consolidated Copper Co., that announced a complete suspension of operations to take place on December 15, has announced that the shut-down will be delayed until January 15. The extension of time is reported to be due to the success of General P. Elias Calles, acting for the Mexican government, in securing for the company a rebate of \$50,000 in taxes.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Gilbert Rigg is in Burma.

Marshall D. Draper is here.

P. K. Lucke has returned to Mexico City from Europe.

F. Castanier has returned from Korea to Besseges, in France.

Roy N. Ferguson has returned from Poland to San Jose, California.

H. B. Tooker, traffic manager for the Jackling interests, is in New York.

L. S. Cates has returned to Salt Lake City after a trip to Boston and New York.

Charles Butters has gone to Copala, Mexico, and expects to go from there to Peru.

Walter Fitch, president of the Chief Consolidated Mining Co. at Eureka, Utah, is at Washington.

J. E. Bloom, Major U. S. Army, retired, has arrived in San Francisco from Brooklyn, New York.

P. B. McDonald, of New York University, is editing a book on steam-heating for Warren Webster & Co.

H. R. Robbins is at Minneapolis, supervising some ore-tests at the State Mines Experiment Station.

J. D. Shilling, general superintendent of the Utah Copper mine at Bingham, has returned home after a trip to Florida.

B. V. Barton has been appointed assistant general manager for the Bendigo Amalgamated Goldfields at Bendigo, Victoria.

L. V. Waterhouse, formerly mill superintendent at Mount Lyell, has been appointed manager for the Mount Hope, Ltd., in Tasmania.

Louis D. Huntoon and G. D. Van Arsdale have formed a partnership, as consulting engineers, with offices at New York and Los Angeles.

W. A. Prichard, manager for the Pato and Nechi dredging companies in Colombia, is on his way to New York, whence he returns to the mines.

G. A. Joslin, managing engineer for the Ramshorn Mines Co., has spent the summer at the mines and mill of the company at Bayhorse, Idaho, and is returning to his office at Salt Lake City.

William Loeb Jr., a director of the A. S. & R. Co., is in Utah visiting the company's smelting plants. R. W. Strauss, assistant to Simon Guggenheim, the president of the same corporation, accompanies Mr. Loeb.

L. W. Hope, who has been superintendent for the Eureka-Holly Mining Co. at Eureka, Nevada, for the past three years, is now holding a similar position with the Ocoee Copper Co. at Ducktown, Tennessee.

N. C. Sheridan, general manager for the Snake & Opportunity Mines Co., Hillsboro, New Mexico, will have charge of the Midnight property at Mullan, Idaho, operations having been suspended at the Snake & Opportunity.

OBITUARY

George O. Kelsey, age 59, a mining man of Cherry Creek, Nevada, died at the home of his daughter, Mrs. Adrienne Reeves, at Salt Lake City, on December 10. He was a native of Utah, but spent the greater portion of his life in California and Nevada in the mining business. He is survived by two daughters.

THE METAL MARKET

METAL PRICES

San Francisco, December 14

Aluminum dust, cents per pound	65
Antimony, cents per pound	9.50
Copper, electrolytic, cents per pound	15.00—15.50
Lead, pig, cents per pound	5.25—6.25
Platinum, pure, per ounce	\$95
Platinum, 10% Iridium, per ounce	\$125
Quicksilver, per flask of 75 lb.	\$55
Spelter, cents per pound	8.50
Zinc dust, cents per pound	12.50—13.00

EASTERN METAL MARKET

(By wire from New York)

December 13.—Copper is quiet and steady. Lead is inactive and firm. Zinc is dull and easy.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 48.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

A NATIONAL BUDGET

Why governmental economy and efficiency, tax revision, and a budget system are essentials preached both at and by Congress, and why it is highly desirable that Congress and the departments should practise them, is again made evident by the preliminary estimates just submitted by the Secretary of the Treasury. He is in this respect simply a messenger, transmitting the department estimates to congressional judgment. Even with all possible paring later, the result will weigh heavily on the American taxpayer, says the Boston News Bureau.

The forecast for the fiscal year 1921-22 is given as \$4,068,000,000, exclusive of postal service. This compares with a similar request for \$4,473,000,000 for 1920-21, or a retrenchment of \$405,000,000. After the supplemental estimates for the current year were in, the total asked rose to \$4,672,000,000. Congress pruned this down to an appropriated total of \$3,213,000,000. Can Congress again cut off a billion and a half?

The announced intention toward allowances and payrolls is emphatic enough; but the power to act is limited by two obvious factors. One is the degree to which the great bulk of Government expense is a fixed "overhead" obligation. It has been figured that in tinkering with Federal payroll, considerably less than a dime out of each Government-spent dollar is at stake. The other element is the need to include certain items of assured obligation yet undetermined.

Thus the Government will eventually have to make payment, now delayed and under litigation, of over \$400,000,000 to the railroads as guaranty of earnings for the first half-year after return to private ownership. All but a few roads accepted the guaranty. Only a few in the past six months have shown net profits to the Government above the guaranty. Then there are strong political prospects for some further wage-advances sought by needy Federal employees, particularly in the Postoffice. Also there is the question of naval expansion. The President-elect has just declared that we should have the largest navy.

It will not be the simplest among the many vexing problems ahead of Congress to trim down the appropriation totals. How these have grown in recent fiscal years may be illustrated as follows:

Year	1921	1920	1919	1918
1921	\$3,213,042,484	1016	\$678,677,858	
1920	4,850,169,029	1915	874,497,825	
1919	25,598,967,517	1914	684,757,278	
1918	18,144,861,745	1913	617,382,178	
1917	1,178,908,962	1912	634,549,561	

How large is the fixed quantity of expense is evident from the fact that of the four billions suggested, almost \$1,900,000,000 must go for debt service in interest and sinking-fund, while \$265,000,000 is allocated to pensions, to say nothing of army and navy.

Heavy sale by the Bank of France has been an important factor in the decline in silver, the decrease in the Bank's silver-reserves amounted to 5,644,000 gold francs for the week ended December 2.

MONEY AND EXCHANGE

Foreign quotations on December 14 are as follows:

Sterling, dollars:	Cable	3.45 1/2
	Demand	3.46 1/2
Francs, cents:	Cable	5.89
	Demand	5.93
Lire, cents:	Demand	3.55
Marks, cents		1.41

Eastern Metal Market

New York, December 8.

There is a better tone to nearly all the markets, especially zinc and copper. While prices are not generally higher, except in one case, they are all firmer.

The tone of the copper market is distinctly better. Prices are firmer.

The tin market is still stagnant but prices are a little higher.

Lead has gone to new low levels but it is felt the bottom has been reached.

Prices for zinc are considerably higher, a better demand not being met by sellers.

Antimony is a little lower.

IRON AND STEEL

The steel trade had expected to drift through December with buying at the lowest rate of the year and the dropping of prices in practically all lines to the Steel Corporation level makes scarcely a ripple. One effect has been to check cancellations and suspensions through a revision of some contracts with independent mills to the new basis. Adjustment of operations to the curtailed demand goes on both at blast-furnaces and steel-works. Pig-iron output in November was 2,934,908 tons, or 97,830 tons per day, as against 3,292,597 tons in October, or 106,212 tons per day.

At 452,000 tons, iron and steel exports in October were the largest for the year, save in July; but current export orders are less than one-fifth of the year's average, with exchange conditions growing worse rather than better.

COPPER

Copper sold last week at 13.50c., New York, but since then the tendency has been upward. There is less desire to cut prices and more stability is in evidence. Dealers are turning buyers rather than sellers and it is almost impossible to purchase electrolytic copper in the outside market under 14c., New York, for early delivery. All asking prices are 14c., which we quote as the market for early delivery with first quarter at 14.25c., New York. Buying demand has not increased perceptibly but it is expected to develop, as the belief is now general that the bottom of the market has been reached. Production is being or has been curtailed quite decidedly.

TIN

The course of the market continues dull with consumers and even dealers indifferent. There have been no important developments. The only news item of special market interest is the cabled press report to a New York newspaper, but unconfirmed in the trade as yet, that the Malay government has fixed a minimum price on Straits tin equivalent to £226 per ton c.i.f. New York. The meaning of this is variously regarded, some stating it to be a bearish rather than a bull argument or factor. There is almost no trading except the picking of cheap lots when offered. The only sale on the New York Metal Exchange in the last week was 25 tons of Straits tin for February shipment at 34.75c. on Monday, December 6. The New York quotation for spot Straits in the last week has been generally higher, due to speculative operations in London. Yesterday the quotation was 35c., New York, against 33.50c. a week ago. In London yesterday spot standard tin was quoted at £223 10s. against £207 10s. a week ago, future standard at £227 15s. as contrasted with £212 a week ago and spot Straits at £224 5s. against £208 a week ago, which shows the extent of the speculative rise there. Total imports to December 1 this year have been 48,093 tons, against 29,956 tons to December 1, 1919. Arrivals thus far in December have been 1495 tons with 2530 tons reported afloat.

LEAD

The feature of this market has been the announcement of two reductions in the past week of 1c. per pound each in the price of the American Smelting & Refining Co. Late on November 30 the reduction was from 6c. to 5.50c. and late December 3 from 5.50c. to 5c., both New York and St. Louis. It may be said that both the trust and the independent markets are now on the 5c., New York and St. Louis, level. Since this has occurred there has sprung up a good demand which is attracting buyers and there is a feeling that the bottom has been touched. Many inquiries are developing which are spread over the first quarter. Independent producers are not generally selling at the present level, especially for first quarter. There is an evident resistance to any further decline and the tone of the market is better and firmer than in some time.

ZINC

A complete change has come over this market. Demand has improved and prices have risen quite sharply. From a low of 5.60c., St. Louis, last week prime Western is now 6.25c., St. Louis, for early delivery. This sudden change is explained, not by any advance in London, but by a disinclination of producers in general to sell at profitless prices and hence not to meet the better demand that has appeared. This has come largely from galvanizers but, relative to normal times, it is not large. Production has been heavily curtailed. So far as forward deliveries are concerned there is still less of a disposition to sell owing to the belief that the market must advance as well as to no desire on the part of producers to commit themselves to a losing business.

ANTIMONY

The market is a little weaker with wholesale lots for early delivery quoted at 5.65c., New York, duty paid.

ALUMINUM

The leading interest has reduced its price to 26 to 27c. f.o.b. producer's plant for wholesale lots of virgin metal, 98 to 99% pure, for early delivery, while from other sellers the same grade is quoted at 24 to 25c. per pound, New York.

ORES

Tungsten: The absence of business continues. Now that Congress is again in session interest in the tariff bill on tungsten has been revived and there are hopes of its early attention. Quotations continue nominal at \$4 per unit for Chinese ore and \$5 for Bolivian. In England the ore quotation is 24 shillings per unit.

Ferro-tungsten can now be bought at 59c. per pound of contained tungsten.

Molybdenum: There is no demand and prices are nominal at 50 to 60c. per pound of MoS₂ in regular concentrate.

Manganese: Business is at a standstill with quotations nominal at 42 to 50c. per unit, seaboard. Imports continue high, those for October having been 44,700 gross tons, bringing the total to November 1 to 467,712 tons against 285,274 tons to November 1, 1919.

Manganese-Iron Alloys: There is a distinct absence of business in ferro-manganese and spiegeleisen. American producers of the former are quoting \$150, delivered, while the British asking price stands at \$170, seaboard, in the absence of any test of the market. Production and imports continue heavy. According to blast-furnace reports in 'The Iron Age' for November the output of ferro-manganese was 23,153 tons or fully equal to former records for the year. Imports in October were 6700 tons, bringing the total to November 1 to 46,739 tons or over twice the imports a year ago of 22,674 tons. Spiegeleisen is inactive at \$72.50, furnace, for the 21% alloy.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

DODGE ELECTRIC GENERATING APPARATUS

One of the latest and most notable developments of the Dodge Sales & Engineering Co. of Mishawaka, Indiana, consists of complete power-units for electric generating. The units as made by this organization involve no freak ideas or pet hobbies. Every test made on the complete unit is made in strict accordance with the rules adopted by the American Institute of Electrical Engineers.

The generating units are made up either direct connected or belted in all standard voltages using Dodge heavy-oil engines as motive power. The sizes manufactured at pres-

fuel-cost chart illustrated herewith, however, are based on 0.5 lb. per b.hp.-hr.

The engine illustrated herewith has a brake-output of 50 hp., and is direct connected to a 30-kw., 220-volt, D. C. generator, running at a normal speed of 425 r.p.m. It would therefore use 10,000 gallons of fuel-oil per year, if operated 10 hours per day under full load for 300 days. This fuel costs on the average 5c. per gallon and would mean a total of \$500 for annual fuel-cost. This reduces the fuel-cost of current to \$0.005 per kw.-hr. The comparative cost-table clearly indicates the economy of the operation of the Dodge

Dodge Oil-Engine Generator Unit

ent range from 12½ hp. to and including 75 hp. The wide range of sizes makes the fact evident that the power units are equally adaptable to either marine or stationary power-plant service.

The Dodge heavy-oil engine used is sufficient guarantee of low-cost operation which, of course, results in a great saving in the cost of current generation. The Dodge heavy-oil engine is sold under a standard guarantee which specifies a consumption of fuel-oil of 0.5 lb. per b.hp.-hr., using fuel as low as 0.28°B., containing not less than 18,500 B.t.u. per pound. In fact every Dodge heavy-oil engine turned out must use less than the amount guaranteed on actual brake test; otherwise such a guarantee could not be made with any degree of safety. The figures used in the comparative

heavy-oil engine in direct comparison with coal, kerosene, or gasoline engine-fuel.

Some interesting conclusions are definitely and accurately arrived at in this table. For example, it is found that operating under the same period with a simple steam engine would increase the fuel-cost to \$1755, with a resultant fuel-cost of \$0.0157 per kw.-hr. The table also contains figures relating to the operating cost of internal-combustion engines of the same horse-power rating and using both kerosene and gasoline as fuel.

The generator used has been developed especially for this particular service by the Engberg Electrical & Mechanical Works at St. Joseph, Michigan. The armature is of the iron-clad ventilated type, with laminated core, being built of

electrical sheet-steel, thoroughly japanned before assembling. The drum and core are provided with air-ducts, permitting a thorough circulation of air through same.

Nothing but the best double-covered magnet wire of the highest conductivity is used, and the insulation is thoroughly waterproof. A desirable feature in connection with the armature is that it has been so designed as to eliminate a coupling on the armature-shaft, the crankshaft coupling is directly connected to the armature-drum, by such construction

FUEL COST FOR 50 H.P. DODGE HEAVY OIL ENGINE DIRECT CONNECTED TO 30 K.W. GENERATOR	HEAVY OIL ENGINE FUEL @ .05 PER GAL. 5 LB. PER B.H.P. HR.	COAL @ 5.50 PER TON 1190 B.T.U. PER LB.	KEROSENE ENGINE FUEL @ .20 PER GAL. 13 LB. PER B.H.P. HR.	GASOLINE ENGINE FUEL @ .30 PER GAL. 13 LB. PER B.H.P. HR.

1 H.P. Hr. 1 K.W. Hr.	.003 .005	.017 .017	.039 .065	.059 .098

Comparative-Cost Table

that the engine drives through the armature and not on the armature-shaft. This method of construction is substantial and makes it easy to remove the armature; in fact this can be done without disturbing the engine in any manner whatever. Close regulation is assured by having the flywheel of the engine placed close-up to the armature and on the same end of the crankshaft.

The commutator is made of copper bars, insulated with the best grade of mica plate and is very heavy, thus ensuring years of continuous operation without need of renewal. It is built up on a separate sleeve and bolted to the

armature drum, so that the shaft can be removed without disturbing the windings. The bars are collected in a steel chuck, especially designed for this particular purpose, which is provided with large steel screws. The chuck is heated and allowed to expand, at which time screws are tightened to the extreme. When the chuck cools and shrinks, the commutator is drawn into a perfect and lasting position.

Every part of both the Dodge heavy-oil engine and the generator is of the highest possible grade in regard to material, workmanship, and design. All bearings are extremely large and accurately fitted, thus assuring smooth and constant operation with comparatively little attention.

Both engine and generator are carefully tested and inspected at frequent intervals during the course of construction. Both are mounted on a heavy cast-iron sub-base and doweled in place, after which they are subjected to a final operating-test under load.

An indication that concerns requiring electric-generating apparatus have not been slow in appreciating the great economy effected in the use of oil-driven generating-sets is evidenced by the number of orders that have been placed for the units illustrated.

COMMERCIAL PARAGRAPHS

The Chicago Pneumatic Tool Co. announces the removal of its rock-drill manufacturing plant from 864 East 72nd St., Cleveland, Ohio, to the company's Boyer pneumatic-hammer plant at 1301 Second Blvd., Detroit, Michigan. The location of the company's Little Giant air-drill plant at 1241 East 49th St., Cleveland, remains unchanged.

The Thornley coalometer, for detecting excessive temperatures in piles of stored coal and informing the owner of the condition of his stock of fuel, is manufactured and sold by F. C. Thornley & Co., Inc., whose office is at 31 W. 43rd street, New York. The methods of using the instrument were detailed in the 'Industrial Progress' section of the 'Press' of November 27, 1920.

The Falls Rivet Co., of Kent, Ohio, has just purchased from the Ohio Wire Manufacturing Co. of Akron, all the machinery, patents, and patterns relating to the manufacturing of cotter-pins and flat-spring keys. The machinery has been moved from Akron to Kent and is now in operation. The Ohio Wire Goods Co. will discontinue the manufacturing of these articles. The event marks an era of expansion in the business of the Falls Rivet Co., which will add to its established product of rivets, bolts, and nuts. The cotter-pins in question have two well-known points of merit; the pointed feature which permits the pin to enter the hole readily, and the self-spreading feature. Some users have made a saving of 40% in the time required to insert and open a cotter-pin of the old type.

E. A. Williams Jr., president of the Garford Motor Truck Co., of Lima, Ohio, who has been conspicuous in agitating good-roads issues during the incumbency of President Wilson and the last Congress, expresses the hope that the new order of affairs under Republican control also will include a broad constructive policy of road building. Mr. Williams pointed out that figures available at the Garford general offices show that of approximately 2,000,000 miles of highways in this country, less than one-tenth are improved. "This is a condition that should be remedied," he said. "The business of this nation depends upon its distribution facilities and the success or failure of business lies in the intelligent utilization of these facilities. If business is to expand it must have highway development. A nation can reap more profit from a thoroughly-connected properly-constructed system of good roads than from anything else. It is imperative that we have such a system to handle the constantly increasing need for cheap and efficient transportation of foodstuffs and manufactured articles."

A YANKEE ENGINEER	899

An appreciation of the career and character of Arthur DeW. Foote of the North Star Mines, at Grass Valley. His early work at this mine, especially in compressed-air machinery. Tributes to his skill and kindness from former associates. A side-light from one of Mrs. Foote's books. Civil engineering and mining engineering, and their reactions. The humane factor in mine management.

IMMIGRATION	900
-------------------	-----

Statistics for the fiscal year. Small net increase. Sources of the present flow of immigration. The attempt to restrict it by Congressional act.

ARTICLES

ARTHUR DEWINT FOOTE, OF GRASS VALLEY

An Interview, By T. A. Rickard..... 901

A native of Connecticut at the age of 24 seeks adventure in San Francisco. Goes to work as engineer on the Sutro tunnel in 1873. Experience on the Comstock; at New Almaden; at the Homestake in South Dakota; at Leadville. James D. Hague and the opening of the North Star mine at Grass Valley. Unwatering and developing the property. Sundry mechanical problems in equipping the mine. Some ideas on industrial relations. The North Star today.

METHODS OF ORE-SAMPLING IN MONTANA—II

By H. B. Pulsifier 907

Pipe-sampling on suitable material is cheap and accurate. Reducing lot samples to laboratory size.

The use of the riffle-cutter. Probability in sampling. Equipment used in the sampling-mills of Montana; Washoe and East Butte plants at Butte; No. 1 plant of the A. S. & R. Co. at Helena; Anaconda Copper company's sampler at Anaconda.

THE MECHANISM OF THE SURFACE PHENOMENA OF FLOTATION

By Irving Langmuir 913

Little progress in the development of a satisfactory scientific explanation. The theory of adsorption and of surface-tension. Surface phenomena. Films. Measurement of molecules. Experiments with 'clean' and oiled glass surfaces. Measurement of contact-angles of drops of water on oiled surfaces. Experimental results discussed. Application to the theory of flotation as a metallurgical process.

PUMP FOR ELEVATING TAILING 918

An automatic device for protecting a tailing-pump in emergencies.

T. A. RICKARD, . . . Editor

ON February 28 and succeeding six days the Northwest Mining Convention will be in session at Spokane, Washington. This is a regional gathering of mining men, especially of prospectors and small operators in the districts tributary to Spokane. A good program has been arranged by Mr. L. K. Armstrong, chairman of the executive committee.

SECRETARY PAYNE, of the Department of the Interior, has issued a statement concerning the work of the War Minerals Relief Commission. Up to November 27, he says, the Commission had examined 1203 cases and made recommendations in 1124 cases; it had awarded \$2,357,491 upon claims aggregating \$15,827,479, that is, less than 15%. Evidently the percentage of disappointment will be large.

THE time for doing assessment work on mining locations on account of the year 1920 has been extended until July 1, 1921, in accordance with the bill introduced in the Senate and recommended by the Mines Committee of the House on December 15. This bill was passed on December 20, in preference to pressing the one introduced in the House, which would have dispensed entirely with the performance of assessment work on account of 1920, as was done during the years of the War. It was deemed wise not to press the House bill, to which there was considerable opposition; instead, all the friends of the miner joined in asking for the six-months extension. This has been granted.

AT this season of goodwill it is timely to quote from a letter just received from a Californian mining engineer residing in London and practising his profession there. We asked him to what extent the sentiments evoked by the War have restricted the scope for American mining engineers among British operators abroad. He replies that he has "met with only the best of treatment, most courteous in every respect". He had been elected a director of a company and later he had been appointed consulting engineer, the latter being the more profitable, and more important, appointment, of course. There is no "anti-American feeling" in mining circles in London; indeed, he adds, an Englishman has asked him to enter into partnership with him, and that, he suggests, the other man would not have done if there had been any prejudice against Americans. We mention this

to correct an impression to the contrary that seems to obtain among some of our friends in the profession. Whatever little fusses may arise between the newspapers—not the governments—on opposite sides of the Atlantic, and however much pro-German and Sinn Fein propaganda may unite in striving to make trouble between the English-speaking peoples, we are glad to believe, and to know, that the English-speaking mining engineers are comrades all, pleased to work with one another, and willing always to extend the hand of good-fellowship, whether it be done under one or the other of the two flags that have led the way in exploring and developing the mining regions of the world from Cape Nome to Cape Leeuwin, from the Gila to the Vaal, from Chuquicamata to Cusiwhiriachic, from Pike's Peak to Mount Morgan.

WORKMEN generally will have to choose between a reduction of wages and a loss of employment, just as their employers generally have to face a decrease in profit or a loss of their market. It is a question of descending the ladder or of having it kicked from underneath. One condition that complicates the general and inevitable effort to meet altered economic conditions is the delay on the part of middlemen and retailers to cut their prices in accord with the reduction made by manufacturers and wholesalers. The cost of living would be scaled down in logical consequence of the recession in wholesale prices if only there were not a tacit conspiracy among retailers to postpone their own compliance with the new conditions of business. Sometimes we wish that a Food Administrator still functioned, so that his just but heavy hand might fall upon some of these recalcitrant profiteers, but in default of such a disciplinarian it behooves the press to bring the force of public opinion to bear upon these economic misdemeanants.

FOR several years the Alaska Gold Mines Company has continued to mine and mill gold-bearing rock at Juneau in spite of a considerable operating loss; moreover, it is evident that the enterprise is a failure as a mining venture and that there is no expectation of profitable operations even under improved economic conditions; in fact, an official in New York is quoted recently as explaining the continued running of the plant by the assertion that the company expects to dispose of its power-plant and sundry equipment for use in other industries, the number and diversity of which are con-

stantly increasing in the Territory. The making of paper-pulp is one of them. This statement should serve definitely to establish the status of Alaska Gold; the question arises, if the mine is dead, why is it not abandoned? Because it is cheaper to meet the operating loss than to maintain the equipment after a complete shut-down. Generally when buildings are deserted and machinery is idle, they deteriorate more rapidly than when in use, unless money is continually being spent in caring for and repairing them. The fact that the Alaska Gold Mines Company believes it more economical to operate pending the disposal of its plant offers an interesting side-light on the present dilemma of numerous companies in the United States. Their problem is complicated by sundry other factors. To the producers of copper, zinc, and lead, an argument for suspending operations is that, otherwise, ore-reserves are being depleted, whereas Alaska Gold in reality has no reserves of profitable ore and accordingly can ignore this phase of the question. On the other hand, Alaska Gold has no object in keeping its underground workings in condition for future mining. The current work of maintaining shafts, drifts, and stopes, with the attendant replacement of timbers, is expensive; in a large mine it may amount to hundreds of dollars per day and the work must go on whether ore is being produced or not. Probably the most important reason for continuing to mine in spite of an operating deficit is the desire to keep intact as far as possible the essential parts of the working organization. The wise manager realizes that he has an invaluable asset in a group of men, each of whom is trained to perform a definite part in the delicately adjusted human machine. A good many Western mines working on a curtailed scale seemingly are losing more than Alaska Gold; however, as a matter of fact, they have doubtless calculated as accurately as possible the money value of that intangible asset, their organization, and it apparently has been the determining factor in deciding them to continue production pending an improvement in economic conditions.

FOR the first time in history, gold rather than silver, is wanted in India; that country is actually exporting silver to purchase gold. Sundry events that have a bearing on this condition are discussed in a recent article in 'The Annalist' by Mr. C. C. Latour. In 1893, there was established in India a gold-exchange standard in order to avoid the fluctuation of exchange-rates such as exists in China today. British gold sovereigns and Indian silver rupees were made legal tender in unlimited amount; the ratio of 1:15 was arbitrarily established, that being equivalent to fixing the value of the rupee at 16 pence or 32.44 cents. It should be remembered that it is 'sterling' exchange, not the value of the British sovereign, that fluctuates. When in 1917 the price of silver began to increase, the bullion value of the rupee so far exceeded the exchange-value that the Indian government was compelled, in order to prevent wholesale melting of coins, gradually to increase the official rate of exchange until, toward the end of 1919, the rate stood at 28 pence or

56.77 cents. In order, among other things, to divorce the rupee from depreciated sterling it was decided, after mature consideration, to fix again an arbitrary ratio between the sovereign and the rupee, this time at 1:10, or on the basis of 48.66 cents per rupee. This went into effect at the time when sterling exchange was at its lowest level in New York, and the consequence was a large increase in remittances to London, by means of reverse councils, a form of government draft. The issue of these drafts artificially supported the rate of exchange for the time being, but it could not be continued for the reason that about this time India's export trade began to dwindle; indeed, during recent months Indian imports have exceeded exports, the gross value of imports in August being 300 million rupees as compared with 200 million rupees of exports. This condition was without precedent. India's system of finance, currency, and exchange is exceedingly complicated, and it is no wonder that economists often disagree as to causes and effects. However, India is now exporting silver, whereas a year ago there was an almost insatiable demand for it, the Pittman Act being the direct outcome of this absorption. In the early months of this year India obtained practically all the gold produced in South Africa, because of the fact that the depreciation in sterling in Calcutta was greater than in New York. Now the exchange position of Japan is such that she can draw gold both from the United States and from India. Since October more than \$21,000,000 worth of gold bullion has been shipped from India to Japan, this too in spite of the new preference of the Hindoo inhabitants for gold and the consequent demand for it in the bazaars. If this demand becomes great enough, there will be an artificial premium on gold in India that will make shipments unprofitable, despite the existing unfavorable exchange-rate. The discussion is pertinent to our own gold problem in that it demonstrates clearly the fluidity of the world's stock of gold. This is a fact not sufficiently appreciated. International balances of trade and rates of exchange govern the channel and the direction in which gold will flow, and the production of new gold in the United States or elsewhere must be considered only in relation to the entire world's supply.

LITIGATION between Minerals Separation and the Miami Copper Company has been advanced one stage further. On December 9 Judge Woolley in the Circuit Court of Appeals pronounced his decision, on appeal by Minerals Separation from the District Court, affirming the orders of the District Court and holding that the modifications or changes made by the defendant in its milling practice since September 1915 were not plainly mere colorable equivalents of procedures found to infringe. He held further that the practice of issuing supplementary injunctions is not to be adopted in the Third Circuit and that "the remedies against infringement after decree are those which now prevail, namely, damages and profits on accounting, attachment for contempt, and original bill. In the last the patentee's right

to injunctive relief is fully preserved to him". The Court stated: "We have read and carefully studied the entire record. . . . We shall not re-state the law of the case, but shall address ourselves solely to the new facts. These embody at least eleven new procedures or modifications of procedures charged to be infringements because equivalents of the infringements found by this Court in its decree. The processes decreed to be infringements were made up of several steps in which it was found, speaking generally, that infringements were completed before the pulp had reached the Callow cells. In none of the eleven modified processes, again speaking generally, is there a centrifugal pump or a break in the circuit or a pachuca, means or steps held potential in infringements found. In the later modified procedures Callow cells are employed exclusive of and inclusive with other means, in some instances with no prior agitation, in other instances with prior agitation without aeration, in still other instances with prior agitation and aeration, indicating agitation in degrees varying as greatly as the adjectives used in describing it; but whether in any of them there is agitation of the kind, in the degree, and for the duration contemplated by the patent is not so clear and unclouded as to make the newly alleged infringing procedures free from doubt and to warrant the extraordinary remedy of supplementary injunctive relief. . . . To avoid the appearance of affirming the Court's decree upon the negative quality of a finding that we discern no error in its order, we go further and say, that, having made the law of the case we are presumed to know what it is, and that, applying the law to the facts, which, in defendant's motion to dismiss are regarded most favorable to the plaintiffs, we would have made the same disposition of the case had we been sitting in the District Court when the application for a supplementary injunction was made. We are of opinion therefore that the order or orders of the District Court should be affirmed and the case be proceeded with expeditiously and in a manner consistent with the law." The accounting is now before a Master, having been referred to him, by order of the District Court, late in 1917. We expect shortly to publish an analysis of the present status of flotation litigation.

A Yankee Engineer

Among the pine-clad slopes of the Sierra Nevada, on the Pacific side and overlooking the central valley of California, is a pretty settlement called Grass Valley. It is a community devoted to gold mining and is distinguished among other Californian mining centres as the locality where was started the first digging into hard rock for gold-bearing quartz in veins or lodes, following the early washing of the gravel in the river-beds from which the miners of '49 drew their riches. In 1851 the first shaft was sunk on Massachusetts hill; now the Empire mine has a vertical depth of 2705 feet and the North Star is 2500 feet deep; but these figures fail to measure the extent of the mining operations, because the North Star shaft, for example, follows the dip of a flat vein so that it is 6300 feet long from top to bottom, where, by

the way, it is just a hundred feet below sea-level. The North Star has had its vicissitudes, like most mines, but it has been yielding gold almost continuously for 25 years. Moreover, it has been a mining school to a number of engineers now playing a useful part in the world. Originally it was an undertaking launched by that fine old gentleman, James D. Hague, and it was opened up under the technical direction of another engineer of the old school, the school of scholars and gentlemen. We publish an interview with the veteran manager, Mr. Arthur DeW. Foote, now partly retired and succeeded by his son. The story of the big men connected with the big mines is more interesting, we venture to suggest, than the statistics of production or than even the evolution of technical processes. Mr. Foote is a representative American, in his ancestry, his early environment, his schooling, and the venturesome beginnings of his professional career. The interview shows that he is direct and outspoken, eschewing periphrasis. He speaks of men as he found them, and he had to deal with many kinds, but in all his dealings he asserted the essential manhood and self-respect that we like to consider peculiarly American. He could look any man in the face, and, if necessary, tell him to go to hell; but he did not say it too often, and he never said it without cause. He was always kindly and polite to those with whom he worked, either as subordinate or chief. Mr. William Hood, the veteran railroad engineer, to whom Mr. Foote was assistant 45 years ago, tells us that he was "exceedingly competent in his work and a most agreeable gentleman, with whom it was a pleasure and privilege to be associated". Another veteran engineer, Mr. Edward A. Rix, says that Mr. Foote impressed him always as "singularly fair and just in his dealings". He is a civil mining engineer in a double sense; beginning with tunnel and railroad work, he turned to hydraulic engineering on a large scale and then drifted into mining and metallurgy. His early training made him keen in the selection of the machinery employed in mining and more particularly the use of compressed air, for pumping and hoisting, as well as drilling. In this branch of mechanical engineering he was a pioneer, and, as the interview records, he found keen pleasure in planning and devising (with Mr. Rix, a specialist) new types of compressed-air machines, which were then, 25 years ago, in their infancy of development. He had the courage of his convictions, reinforced by a thorough knowledge of the principles involved. For example, the ordering of the 18-ft. direct-connected Pelton water-wheel, which actuated the first compressor at the North Star, required some nerve, for it was of much larger diameter than any previously constructed and was built with spokes in tension like a bicycle-wheel. Mr. Rix says: "The usual knockers lined the fences to see her blow up when started, but they were disappointed." Mr. Foote has decided ideas on education, more particularly the need for teaching English to engineering students. He becomes explosive in talking of the jargon that is the accepted medium of literary communication among members of the profession. He has an understanding sympathy for the toilers underground and recognizes that

the entire morale of a working force depends upon the personality of the manager, superintendent, and foreman. He places his finger on the weak spot of industrial management, namely, the increase in the size of the operations and the number of men employed to such an extent that personal influence becomes extinguished and the relation of a manager toward his employees becomes dehumanized. That is repellant to him, for his traditions and his education alike have given him a feeling of keen responsibility to the men whose work he directs and an appreciation of their troubles and distempers. He is like the type of Colonel who is a father to his regiment. Which reminds us that he appears disguised by literary art in a book called 'The Ground Swell', written by his wife, who, as Mary Hallock Foote, is known to many of our readers as the author of 'The Led Horse Claim', 'The Valley Road', 'The Chosen Valley', and a number of other books in which the refined imagination and the tender feeling of a New England gentlewoman give charm and reality to divers phases of Western life. In the retired General of 'The Ground Swell' we catch glimpses of our mining engineer at Grass Valley. "When he's happy he drops into Uncle Remus talk; when he is very happy he becomes nautical. In his far-off boyhood he had played with boats." Again: "My husband could do foolish things with money, but he had a long-distance wisdom at times that money cannot buy." When things did not go quite right he would describe them humorously, "not being a bitter person". As for example, in his disagreement with Adolf Sutro. It is a great help to one's philosophy of life to be able to see a joke against oneself; indeed it is the supreme test of humor. Looking at Mr. Foote's career as a whole, it may be remarked that a good training in any branch of engineering is a preparation for any other branch of the profession; undoubtedly mining engineering benefits from the incursion of ideas brought to it by competent civil engineers, and there is something in Mr. Foote's remark that the civil engineer or the hydraulic engineer has "a broader education and a broader scope" than the mining engineer; in short, much that the members of our profession are called upon to do is only slightly related to their technical training, but, for that reason, there is more opportunity, we believe, for the play of personal character in mining than in other phases of "the art of directing the great sources of power in Nature for the use and convenience of man". In the exercise of that art it is necessary not only to direct natural sources of power but to direct the energies of human beings, and therein lies its chief interest, difficulty, and importance. Modern industry has developed an ugly aspect, largely because, with all the improvements in mechanics and chemistry, we have not produced a sufficient number of men competent in character to be given the charge of large numbers of their fellow-men. That is the main problem facing our industrial democracy. We need more engineers like Mr. Foote, alert and sagacious, but also humane and sympathetic to those who work *with* him rather than *for* him; in short, the democratic ideal of industry is not serfdom but co-operation.

Immigration

Restriction of immigration is the subject of Congressional legislation just now. In the annual report issued a few days ago by the Department of Labor will be found a set of statistics that are worthy of study. During the last fiscal year, 633,371 aliens arrived in this country, as compared with 237,021 the year before, but 428,062 departed, reducing the net increase to 193,514. This is a much smaller figure than had been anticipated from periodic statements on the subject. Before the War the annual increase due to immigration was about four times as large. In 1914, immigrant aliens numbered 1,218,480 and emigrant aliens 303,338. Of the 2762 ordered deported during the year, 469 were classed as anarchists and criminals. Of the total arrivals 11,795 were sent back. During the past fiscal year 16,174 Japanese arrived and 15,653 departed, leaving 521 as the net increase. It would be well if Federal officials compared their statistical statements and thereby inspire greater confidence in them. For instance, Mr. Anthony Caminetti, Commissioner General of Immigration, says that last year Japanese immigration increased 13%, but he does not say whether that was a net increase. He mentions the interesting fact that there was a net increase of 82,357 from Canada and a net increase of 45,755 from Mexico, these two items making together 66% of the total net gain in our immigrant population. During the year, 519,003 aliens took out either their first or their final papers of naturalization; first papers were filed by 300,106 aliens, while final naturalization was claimed by 166,925 aliens in civil life and 51,972 soldiers. Mr. William B. Wilson, the Secretary for Labor, suggests the establishment of Federal agencies overseas, in co-operation with foreign governments, for the giving of information to expectant emigrants in order that they may know the restrictions to which they will be subject and the conditions that they will face on arrival here, thereby presumably checking the attempt of those who are inadmissible or otherwise unwelcome to our shores. It is obvious, from the official statistics, that the influx of aliens is much smaller than was generally supposed; it is considerably less than is required by the normal expansion of industry in this country. We are informed that there is a considerable influx of Russian Jews of the small-trader class, and also of Italians. The latter make good citizens, especially if they come from northern Italy, but the Russian-Jew peddler type is most undesirable, because he is non-productive, becoming merely a minor middleman, and bringing with him notions of living and of government that are intensely foreign to the American idea. If the attempts to restrict immigration are intelligent, in excluding undesirables, not on account of poverty or race, if white, but on account of incompatibility with our American ideas of life and government, they deserve to be supported; if they are meant merely to strengthen the control of organized labor in this country, they deserve to be opposed, as probably they will, by our representatives in Congress. We hope the bill now before Congress will fail to pass.

THE NORTH STAR MINE AND MILL

Arthur DeWint Foote, of Grass Valley

An Interview, by T. A. Rickard

Mr. Foote, you come of old American stock?

Yes, for eight generations; my ancestors came from Yorkshire in 1630.

Where were you born?

At Guilford, Connecticut, in 1849.

Was your father interested in mining?

No, my people were farmers and soldiers for generations.

That explains your interest in irrigation, and in engineering as applied to the improvement of farms.

I suppose it does; I was interested as a boy in a drainage scheme we had at home.

What was your early education?

Private school and high-school and a short time at the Sheffield Scientific School at Yale in the class of '69, which I left in 1868. My eyes gave out, so I had to stop studying. Then I went to Florida to grow oranges. After a year or two I went back to New York and got my eyes back. The next winter I was in the West Indies. Then I returned to New York and worked in the Atlantic Dock iron-works, in Brooklyn. Later, I was over a year at Washington, laying asphaltum pavements. During this time I was studying more or less on engineering lines. In the fall of 1873 I came to San Francisco.

What brought you here?

I was looking for something to do, and at that time San Francisco was lively.

Did you get a job soon?

Yes; I went up to Virginia City, Nevada, as assistant engineer on the Sutro tunnel.

Under Adolf Sutro?

Yes. Wederkind was chief engineer. He was a Dane who had run the lines for the Hoosac tunnel and came out to the Sutro tunnel as engineer several months after I got there.

Do you recall your impressions of the Comstock and Virginia City?

I had a letter of introduction from James D. Hague to Isaac Requa, the father of Mark L. Requa. He was very civil to me and showed me around. I remember being much impressed by the Cornish pump in the old Chollar-Potosi shaft. I met Ross E. Browne there at that time.

Which impressed you most, Ross Browne or the Cornish pump?

I think Mr. Browne made the most lasting impression. He worked with me on the tunnel some of the time before Wederkind came out. He has been a good friend of mine ever since. I left there in 1874. Sutro fired me. We had struck a flood of water in shaft No. 2 of the tunnel and were drowned out.

Why were you drowned out?

We had to run the pumps so fast that the steam-pipe heated the shaft until it became impossible for men to work. Sutro came to the office, fuming and swearing,

whereupon I told him that we had not been 'drowned out' but we had been 'burned out'. He did not like it, so we parted company. I did not then know that he had put in the steam-pumps against the advice of everybody who understood the subject, because he could buy them for stock in the tunnel company. At that time the only kind of pump that would have served our purpose was the Cornish pump. Today, of course, under similar circumstances, we would use electric pumps. It might be worth while, as a matter of record, to mention that while at the tunnel I helped J. B. Pitchford, who was master mechanic, put up the first air-compressor installed in the West. In fact, there had been but two in the whole country before that: one at the Hoosac tunnel and one at a Delaware & Lackawanna railroad tunnel.

What did you do next?

I went up on the Eldorado canal under F. A. Bishop, on the south fork of the American river. It supplied water to the hydraulic mines around Placerville. I remained there only a matter of eight months. Then I went down on the Southern Pacific railroad to Tehachapi, where I was under William Hood, chief engineer of the Southern Pacific. He was very kind to me and we have been friends ever since. I got tired of the desert country and got back to underground work at New Almaden.

Who was in charge of the New Almaden at that time?

J. B. Randol.

Who was in charge of the engineering staff?

No one but myself. Hamilton Smith came down to look over my work on a difficult piece of surveying, and thereby I became pleasantly acquainted with him, and through him with Henry C. Perkins. I stayed there some three years, and while there, in 1876, I was married to Mary Hallock.

Did you live in the old 'casa'?

No, we lived on the hill; I fixed up a little cabin there. Both of us enjoyed it. My work was absorbing; some of it was quite difficult, and the Mexican element was extremely interesting to my wife. Our son was born there. He is now general manager of the North Star mines, at Grass Valley.

Why did you leave?

Randol and I did not agree.

On technical matters?

No, on general principles. I resigned and went up to Deadwood, South Dakota, where I worked as engineer under Sam McMaster, superintendent of the Homestake. I opened an office on my own account, but most of my work was done for the Homestake Mining Company. The owner, George Hearst, who was in partnership with Haggin and Tevis, was living there at that time.

Was Hearst a good miner?

His principal business was lawsuits. He always claimed he did not know anything about mining, and refused to act on his own judgment. He said, if he went to a dump he would be sure to pick up the only piece of good ore that was on it. He employed Henry Janin, Louis

Janin, and James D. Hague. He himself was dirty, slovenly, and extremely vulgar.

Was there anything in your work at the Homestake of special technical interest?

Well, there was only one point of particular technical interest; that was whether the Homestake and the Old Abe veins came together in depth; but the mines were not opened sufficiently to warrant an opinion. It was thought finally that they would come together, so Hearst bought out the other parties, after trying to beat them in a lawsuit. I was not sorry to leave Deadwood, in '78, to go to Leadville.

Yes, I know you were at Leadville, because I read 'The Led Horse Claim', Mrs. Foote's book, about 35 years ago, and I still recall the charm of it. What took you to Leadville?

My first job was on the Iron Silver suit, as an expert. That lasted up several months. I established an office there and was afterward in charge of the Adelaide and several other small mines.

What was the mine that figures in 'The Led Horse Claim'? As I recall, the story dealt with a lawsuit and trespassing that culminated in fighting underground at the boundaries of two conflicting mining properties.

The foundation of the story was the suit between the Adelaide and the Argentine.

It is generally supposed that the hero was typified by Ferdinand Van Zant.

No, he was a friend of ours and he was my clerk at that time, but a great many incidents in the story were imaginary. It was a picturesque case. When the fellows on the other side broke through below, they drove our men out. Steve Fleming grabbed his Winchester, threw his leg around the rope—a wire rope—and went down, hand over hand. He got to the bottom and ordered them out. They could not see him, of course, but they could hear the click of his rifle—not to mention the language that he used, suitable to the occasion—they went.

Who, among mining engineers, were at Leadville at that time?

Most of them used to come around to us: Clarence King, Rossiter Raymond, S. F. Emmons, James D. Hague, R. E. Booraem, R. W. Emmerson, and many others. Tom Walsh, of Camp Bird fame, was keeping a hotel in Leadville. When I first arrived, I could not get a room, so he took me in most kindly. I had known him at Deadwood.

Was he a carpenter at Deadwood?

No, I think he kept a restaurant there. It was a very pleasant summer in many ways, because Emmons had his camp near our cabin on the outskirts of the town, and we used to have delightful meetings with him and Clarence King, Hague, Raymond, and other men of high character, coming and going. Dr. Raymond wrote a poem on the cabin and sent it back to us. I remember

CANAL OF THE IDAHO MINING & IRRIGATION CO.

twenty years afterward going to his office in New York, and as soon as he saw me enter the room he started to quote this poem of his, 'The Little Log Cabin by the Ditch'.

Can you mention some technical recollections?

Yes, I would mention the fact that at this time James B. Grant, afterward of the Omaha & Grant Smelting Company, and Governor of Colorado, did the first direct smelting of galena without roasting in a blast-furnace—a water-jacketed furnace. Those of us who were in Leadville at that time took a keen interest in the experiment.

How long were you at Leadville?

I was there over two years. Mrs. Foote enjoyed it more than I did, because it was such a contrast to her previous life on the Hudson river and in New York City. She began to write while at Leadville, and her first story was the one that you have already mentioned. It encouraged her to keep on. Before that she had been an illustrator for magazines in New York. My health broke down, owing to the high altitude, which affected my nerves, and I went East for a while. That winter I went to Mexico and stayed down there for several months.

Where?

For a time I was at Morelia in the State of Michoacan. The trip did me lots of good, and on my return I went into the Wood River country, Idaho.

What mines?

I examined several mines, and finally opened up a prospect called the Wolfstone.

Did you name it after the mine at Leadville?

No, it was probably named after the Irish leader. I stayed there until the beginning of the next winter, and while there I became interested in an irrigation project on the Bois  river in the Snake River valley. The land lies between the Bois  and the Snake, forming a peninsula. I took up water-rights on the Bois  river and made

the surveys for a canal to serve some 300,000 acres of land.

On your own account?

I was doing it on behalf of myself and some friends. We organized a company later and called it the Idaho Mining & Irrigation Company. My habits as a miner led me to prospect the bars on the Snake river and to add the word 'mining' to the name of our company.

Did you find anything?

Yes, I found a large area of ground that would pan from 50 cents to a dollar per yard. Eventually, when we got a small canal built and the water on the ground, we washed it as they do on the Snake river, by means of sluices, screens, and blankets. Our blankets we washed in a tub. That was my first experience with cyanide. We put a little cyanide into the tub to brighten the gold, and it immediately dissolved most of the gold, which was very fine and very pure. The clean-ups were disappointing. We did not work long. That was just a year or two before the discovery made by MacArthur and Forrest.

But if the gravel contained from 50 cents to a dollar per yard, surely it will pay to work today?

I presume it would; but at that time we gave our chief attention to the irrigation work. I was there some twelve years and had great difficulty in getting money to build the canal, but finally built a portion of it. Our directors had trouble among themselves, and the enterprise was abandoned. The canal has since been built by the Government. There was never much publicity about it, though it is the largest irrigation canal in America or Europe, having a capacity of over 4000 cubic feet per second; and the Arrow Rock dam, which forms a huge storage reservoir for it, is the highest dam in the world. During that time I was engaged for a couple of years or more on Government work—the first Government irrigation survey in the United States. I had charge of the Snake River division under Major Powell, director of the

U. S. Geological Survey. Those years were extremely interesting with two or three parties running canal-lines on the Snake River desert, preliminary surveys for the irrigation of several million acres, hunting the Grand Teton range for reservoir sites on both forks of the Snake river, through Jackson's Hole, up to the Yellowstone and Henry's lakes.

So then you had to abandon this Boisé project, and you returned to mining?

Mining or quarrying. In 1893 I went to Lower California to open up an onyx deposit, in which Emmons was much interested. In fact, I went down there with him. There was a big mass there of the most beautiful rock you can imagine, but it was 75 miles from the coast. I built the wagon-roads and arranged for putting the material on board ship. Then the panic came on and the enterprise was abandoned. From there, I came up to San Diego, and Hague telegraphed to me to come to Grass Valley. On my arrival he told me of some of his plans for the North Star mine. He told me that he was going to open up the Rocky Bar mine on Massachusetts hill—I mean the one in which the Watts made their money. It was rumored that there was a good deal of water to be encountered, and Hague wanted me to go and see what few electric plants there were then in the West, so I went to the Fremont mine at Amador City and saw their electric pumping equipment. I was to have gone to Bodie, but I did not go. It was just after the Bodie electric line had been completed. But I went to the Calumet & Hecla in Michigan. They had just put in two sets of pumps having a 1600-ft. lift each. I stayed there for a week and learned all I could about them. In January 1895 I came to Grass Valley to open up the group of mines for Hague, who represented what is now the North Star Mines Company.

This company has an interesting proprietary.

Yes, we had a fine lot of shareholders. The Agnews and Blisses of New York, the Phelps Dodge people, including James Douglas. J. P. Morgan was one of the stockholders, also Balfour & Guthrie. Hague himself had a large interest.

The first time that I visited the North Star mine, Emile Rector Abadie was the superintendent. That must have been in 1886, because I remember being interested in comparing the methods of milling with those used in Gilpin county, Colorado. The next time I was at Grass Valley was on the eve of George Starr's departure from the Empire mine to go to South Africa. That was in 1893. I remember that my first meeting with you was on my return from Australia in 1898, when, like most intelligent mining engineers, I took the opportunity to visit Grass Valley, more particularly the North Star mine. You must have had an enormous number of visitors during your residence at Grass Valley.

Yes, it has been a great deal of pleasure to us to have them come there.

Will you say something about your experience at the

North Star mine, more particularly with reference to its vicissitudes and its success?

I did not agree with Hague about using electric power for pumping. The mechanical application of the power was not sufficiently developed to constitute good engineering; so I put in a compressed-air plant to do our pumping, hoisting, and drilling.

What sort of a plant did you erect?

We were getting our power from water. We bought water, delivered to us at the top of the hill over 2½ miles away, and we let that water down in a pipe to the lowest point of our land and applied it to Pelton water-wheels. Our ditch gave us an 800-ft. head of water, and that, by the use of large water-wheels, enabled us to employ direct-acting compressors.

Of what make were they?

The first two were designed by Edward A. Rix of San Francisco and were very successful. Later we put in two others of our own design.

How long did it take to unwater the old mine?

The mine did not make a great amount of water: four to five hundred gallons a minute. It took us about four months, after we started the pumps, to get to the bottom. That was late in 1896.

Then you began to explore the old workings and open up new ground? Were you put in charge?

After I got the machinery all in, I was appointed superintendent. That was in June 1896. We began sinking, and found that the old shaft was vertical for about 240 ft.; then it went off askew at a flat angle.

So that it was not usable?

Well, I made it work by putting in a vertical curve, as well as a horizontal curve to get into the old incline and then I was obliged to put another horizontal curve into that shaft to get down at right-angles to the vein. It was about as straight as a dog's hind leg. We found a nice body of ore on the 1300 level. We also found a good body of ore up above where the Watts had taken out their bonanza.

What level?

That was above the old workings, probably 200 to 250 ft. from the surface. As we went down, the vein became larger but very poor, and it continued to flatten, so that the conditions became most discouraging. We stopped and abandoned the mine.

That was in?

In 1899.

Had you made any profit over the cost of equipment?

Yes, we had taken out enough to pay for all our trouble and a little more. We took out about \$800,000 worth of gold. In the meantime we started a new vertical shaft to tap the North Star vein at the forty level—that is, as measured on the dip of the vein. The shaft cut the vein at 1600 ft. below the surface in April 1902.

Did you find good ore?

Yes; we found, right at the bottom of the shaft, a

bunch of fair ore. The quartz from the first blast, as it came up, showed little bits of gold in almost every piece. It probably assayed about \$20—an ounce—per ton. Then we cut our station and commenced drifting and put up a raise to reach the bottom of the old shaft. Of course, we encountered a great deal of water. In driving at the 40 level and putting up this raise we often had to plug up the holes to keep the water from drowning the pumps.

But I presume that the pressure was greatly relaxed as the water-plane was lowered?

I presume so. After a year or so this flow of water almost ceased. We extended the 40th level, and then the 37th, and then others in succession. The 37th was the richest level in the mine.

By "rich" what do you mean in terms of feet and dollars?

There was over 2000 ft. on that level that would average \$15 for a width of 2½ ft. in the mill. Near the shaft there was one bunch from which we took out \$16,000 from ore that was so rich that none of it went to the mill. We crushed it up in the assay-office and put it into the crucible to be melted. It was great stuff, I tell you.

The mine has had no set-back since then?

Not until the War raised the prices of everything that we had to buy, and did not raise the price of our product, namely, the gold.

What has been the output of the North Star since you have been connected with it?

I will have to refer to the records for that. They show about 1,600,000 tons averaging \$11.35 per ton, making a gross value of \$18,000,000, from which about five millions have been paid in dividends.

How is the bottom of the mine?

On the 6300 level the North Star meets what we call the 'X' vein, that is to say, a vein coming down from the east at a dip of about 40 degrees. Whether the North Star vein goes through, we don't know yet. Apparently it does not on the south side of the shaft. Meanwhile, the 'X' vein is going down strongly, dipping west, and shows a good width of milling ore scattered in a wide lode.

What is the vertical depth of the 6300-ft. level?

The dip averages 24°, so that level is 2500 ft. below the surface or 100 ft. below sea-level.

Are you doing any work below the 6300?

No. When we shut-down last winter, we stopped all the work on the 63, and now are doing development work and a little stoping on what we call the 'A' vein on the 34, 40, and 47 levels. This 'A' vein connects with the North Star vein between the 40 and 47 levels.

You say that you shut-down last winter. Why?

The mine was not paying owing to the fact that about one-third of the men would not do a fair day's work and would not allow the others to do so. Therefore, we discharged 250 men, retaining 110, doing just stoping enough to pay our overhead expenses and taxes, and a large amount of development work on the 'A' vein.

These 110 men are doing more than two-thirds of the work done previously by the crew of 360.

The men that you have retained, I presume, have homes in Grass Valley?

Yes; they are old men who have been with us for years. They are mostly the sons of Cornishmen who came to Grass Valley in the early days. All the old fellows are pretty well gone.

What do you think of the proposal to levy a tax on manufactured gold under the McFadden Bill? Do you think it will help gold mining in California?

I think it might help gold mining, but I object to it as being special legislation and thus giving an excuse for other special legislation that would injure us about as much as the proposed law might help us.

Are you using flotation in your mill?

No. We made a pretty careful investigation to ascertain if it would be advantageous to us, but we found that the amount we might save would be very nearly eaten up by the royalty and would require a considerable investment. It was a question whether the profit would be sufficient to pay for the investment. The terms of the contract we could get from the Minerals Separation Company disgusted us so much that we told them to go to hell.

Mr. Foote, your son has followed in your footsteps?

Yes; he graduated as civil engineer from the 'Tech,' at Boston in '99 and came as my assistant at the mine in 1904. In 1912 we made him general superintendent, and in 1915 he was made general manager. Meanwhile, I was semi-retired as consulting engineer for the company.

By the way, you had an interesting experience in the Tightner mine, did you not?

We had an experience that was delightful for a time. It was rather interesting. Driving north on the vein, we struck a bunch of quartz about 30 ft. wide and perhaps 100 ft. long. We stoped up on the foot-wall, getting indications of gold; in fact, we milled about 5000 tons, which went \$2.49 per ton. Then, in putting up a raise from the stope, we ran into coarse gold, and worked to the hanging over the former stope of poor quartz, taking out \$750,000 in gold in a space less than 100 ft. square. Some of it was so rich that we had to cut it up with chisels to get it to the mill.

Did you send it to a stamp-mill?

Yes, we put it under the stamps in order to remove the barren quartz, and then milled it.

That is, you used the stamp-mill as a crusher and not as an amalgamator?

Exactly.

I presume that the so-called barren quartz was good enough to be re-treated?

It went right on over the amalgamating-plates in the regular way.

Well, that must have been delightful, but did it happen again?

Not in such a large amount, but we found numerous

bodies that yielded from \$75,000 to \$100,000 in the course of three years.

Did this gold occur above the water-level, or the limit of oxidation?

That is pretty hard to answer, because the apex of the vein is covered by 1000 ft. of lava. The Middle Yuba river near-by is at a level 2000 ft. below the horizon at which we found this gold.

Did you find the outcrop of the vein in the bedrock of the old alluvial channel?

That was where the old miners discovered it and told H. L. Johnson about it, and he opened the old tunnel and found it. That was the origin of the Tighner mine.

How much has the Tighner produced?

Under our management, it has produced about \$1,700,000, and about \$400,000 more for others.

Do you consider mining engineering a good profession for the young men of this generation?

Yes, it is a fine occupation. The mining engineer's life is as interesting as that of a civil engineer, and there is probably more money in it, but the civil engineer or the railroad engineer or the hydraulic engineer has a broader education and a broader scope than the mining engineer.

Have you any suggestion for improving mining education?

Professional education, I suppose you mean. Prof. Christy used to ask me that question and when I suggested reading and writing he seemed disappointed until I explained that by 'reading' I meant reading good literature, historical mining, and geology until the student acquired something of a vocabulary and the proper forms of language, and by 'writing' I meant a cultivated handwriting, and using words intelligently so as to convey ideas clearly with fine distinctions. When a man can do that he has advanced far in his profession.

Have you any particular ideas for the betterment of industrial relations, that is to say, for improving the relations of employer to employee in mining enterprises?

My idea is that the personal equation is everything. The great difficulty is that when you get a large number of men under one management you obliterate that personal equation and so render the relations unhuman. I think the remedy is coming by means of the shop committees, as they call them in England, or grievance committees—an unfortunate name—more properly welfare committees, composed of one man from each gang of workmen to meet with a special representative of the management freely and without prejudice at any and all times. Any serious matter that cannot be arranged by him is brought to the superintendent, and if not then fixed up, is brought before a Board of Conciliation composed of employees and officers in a proper proportion. This welfare man must have the special talent for spreading his personal equation of kindness and reasonableness through all the working force. This man will be difficult to find, but the position is next in importance to

that of the manager and should be treated accordingly.

What do you think about the proposed Department of Public Works to include all the engineering functions of the Federal government?

I think such a Department would save millions of dollars every year and get more, much more, useful work done than is done now. Such a Department organized by and under the direction of Herbert Hoover, taking the place of the Interior Department, would prove so economical and efficient that soon the people would be demanding that all engineering work should be done under it.

What do you consider the prospects of further gold discoveries in the United States?

If you mean absolutely new discoveries, like Cripple Creek, I imagine few are to be made. If you mean new discoveries in small mines and prospect-holes now lying idle or being held by annual assessment work, I think there are great numbers to be made. When gold again reaches its normal value, gold mining will revive and our production will increase and continue for many years beyond our ken. It probably will not be as spectacular as in the past, neither will it be as uncertain. Much has been learned about gold mining, even in the last 25 years, and it seems to me that the future mining will become more and more a manufacturing business managed by trained men, who will take only reasonable risks and will be satisfied with reasonable profits.

What do you consider the most satisfactory experience of your career?

That is a somewhat difficult question. Probably my twenty-odd years at the North Star mine have been the most satisfactory. There were several quite interesting engineering problems to work out: a good hard fight at times, when men had to be held to their work with moral suasion and profanity properly blended. There were times of discouragement, of course. I remember Hague saying to me very pleasantly, "Do you know, Arthur, you have spent over a million dollars since giving us a cent". Mr. Hague was a most delightful man to work for. His sense of humor would dominate any occasion and cover all trouble. He never bothered me with details. His only specification for a stamp-mill that was to cost \$80,000 was, "Build it to last thirty years". So I built the mill of stone and iron, and it was satisfactory. Hague died in 1908, just at the beginning of our reward for ten long years of preparation. That year the mine produced over a million dollars and continued at that rate until war prices shut us down. After James D. Hague died, his son William, or 'Billy' as everyone called him, came out as managing director. He built a house and brought his charming wife out, and his children were born here. As I had turned over the active charge of the properties to my son, I had the pleasure of watching the second generation carrying on the work of their fathers until the War came. Yes. I think I may say that the years from 1895 to 1916 were the most satisfactory or the least unsatisfactory of my life.

Methods of Ore-Sampling in Montana—II

By H. B. Pulsifer

METHODS OF SAMPLING. Methods for sampling may be divided into those carried out by hand and those done by power on a larger scale, commonly called mechanical. The hand methods are mainly cone-and-quarter, fifth-and-tenth shovel, split-shovel, pipe-sampling, and riffle-sampling. Mechanical samplers cut out the sample by some device like a slot, or blade, which separates the stream of ore as it falls past the rotating, oscillating, or vibrating part of the mechanism. The ultimate analysis of nearly all mechanical cutters reveals them as of the intersecting cone, or saucer type. From another angle they can be regarded as the hand-rifle rotating about a vertical axis and with the number of slots reduced to only two, four, or eight.

From the theoretical point of view, all the methods of sampling are mere applications of the probability principle. At one extreme, a lot of substance may be thoroughly mixed, after which any one small selection will correctly represent the original lot; the other extreme is presented by material that is heterogeneous, but by taking enough cuttings, often thousands, the sample will represent the entire lot. In practical work we commonly use the extreme methods or a suitable intermediate process. Cone-and-quarter sampling involves thorough mixing and a limited number of cuts, to which is added an attempt at diagonal compensation afforded by a spread cone; as a working method it is now generally replaced by the use of the stand and table slotted cutters. The riffle-cutter will mix a sample, or divide a sample, with a facility never approached by cone-and-quarter work. Pipe-sampling is probability sampling depending upon from 30 to 100 cuts, on comparatively uniform material.

In the Montana bulletin I described the practice of pipe-sampling at Butte in the following paragraphs.

"PIPE-SAMPLING. Pipe-samplers have long been used in Montana and in other sections of the country, notably at the zinc mines in Missouri and Oklahoma, where the cars of concentrate are sampled with a 'gun', as the pipe-sampler is there called, immediately after loading for the smelters. Since the advent of flotation concentrates, which are notoriously sticky and difficult to handle, the use of pipe-samplers has increased greatly in the Butte district.

Ore suitable for pipe-sampling may be concentrate or other fine material that has been produced in a regular and uniform manner, or has been mixed in handling. Flotation concentrates may vary in moisture from a thin mud to a dry powder. When sampling carloads of the muddy concentrate men are sometimes barely able to stand on the drying crust. Cars that have traveled long distances may have the load so firmly packed that an auger, rather than a pipe, is required to cut the samples.

"According to the Montana practice, lots of concentrate are sampled at the mill by the shipper and later at the custom sampling-plant, or smelter. Data as to agreement of assays are not available, but results are said to be wholly satisfactory.

"Pipe-sampling of a carload of concentrate usually begins at one end of the car, where a row of holes two feet apart and two feet from the end-wall is made; a parallel row is then punched two feet nearer the centre and this is repeated until samples are taken systematically over the entire length of the car from points about two feet apart. Hopper-bottomed cars have the two deep pits, which are hard to penetrate, but the pipes are long enough to touch the steel bottoms, as in the shallower portions of the car.

"Pipes are commonly four to five feet long, three inches diameter at the top and two inches at the cutting edge. For firm materials, easily cleared, circular tubes are used; for sticky loads the pipe is slotted and provided with a scraper with which the sample-man quickly forces the core out into the sample-pan. A sample of 250 lb. is usually obtained by from 40 to 75 insertions of the pipe. Fig. 7 shows three men sampling a car of flotation concentrate at the Washoe sampler.

"Pipe-sampling of fine concentrate may continue in the bucking-room until the final samples for moisture and assay are taken. The sample-man merely goes over the pans containing the first sample with a smaller pipe, a foot long and an inch in diameter, and punches enough cores to give a sample of the required weight.

"The accuracy of pipe-sampling clearly depends on the uniformity of the lot of ore as it is spread in the bin or car. To test the uniformity of concentrate in a railroad car, the author took 40 four-ounce grab-samples from the pipes as a car of flotation concentrate was being sampled at a custom-plant. Each of the samples was dried, ground, mixed, and analyzed for iron with the following results:

Sample	Iron, %	Sample	Iron, %
1	14.7	21	13.4
2	14.2	22	15.5
3	13.8	23	13.1
4	14.5	24	13.1
5	14.0	25	13.1
6	14.2	26	18.3
7	14.3	27	13.8
8	14.1	28	14.5
9	15.0	29	14.8
10	13.0	30	15.0
11	14.1	31	14.8
12	14.8	32	16.2
13	14.5	33	15.7
14	13.8	34	16.3
15	14.5	35	17.2
16	14.1	36	15.4
17	13.2	37	14.8
18	13.6	38	15.3
19	12.8	39	17.4
20	15.0	40	14.3

"The average of all is 14.7%, and the average deviation

tion of a single analysis is only 0.9% from 14.7%. In other words, the average deviation from the mean is approximately one part in fifteen. From the sampling point of view it means that one could take a grab-sample anywhere in the car and the probable analysis of that sample would be accurate to closer than one part in fifteen.

"The main pipe-samples, from which the little samples just discussed were taken, weighed 25 to 30 times as much and were piled and again piped before drying, mixing, and grinding for the regular sample. The main sampling work might reasonably be expected to be 10 times as accurate as the author's grab-sampling, which would make the main pipe sampling accurate to more than one part in 150, a precision considerably greater than ordinary assaying or wet chemical analysis.

"Pipe-sampling of fine mixed materials is rapid and cheap; the test confirms the prevalent opinion that it is also accurate."

The use of the stand-riffle as an instrument for mixing and cutting samples is justified by the large number of cuts which can be made with slight effort. Thousands of cuts are made when fine ore or pulp is shaken across the top of the row of riffles; every condition thus favors the free play of the law of probability, namely, that the greater the number of cuts the more nearly the composition of the sample will approach the composition of the entire lot. In the Montana bulletin the subject of riffles was discussed under the heading of 'Mixing the Sample'.

"The mixing of a large lot of ore consisting of large and small pieces is almost impossible and, besides, is wholly useless. When you try to do this you find that any method of handling assorted sizes allows segregation if the material is dropped, or let roll, or even moved by ordinary implements. The material cannot be properly sampled by small selections of single pieces, because the larger pieces exceed the proportionate composition in all components.

"The mixing of large lots of fine ore or mill-products is not as difficult an operation as the preceding, but is seldom practicable unless done incidentally in the production or transfer of the material. Even if a lot of fine ore appears to be uniformly mixed there is no easy demonstration of the fact, and it is much safer to depend on a considerable number of cuttings. The frequent division of a fairly uniform material is carried out in practice when mill-streams are sampled, either mechanically or by hand, when cars and bins of concentrate are pipe-sampled, and in shovel-sampling by the tenth or fifth shovel method. The three methods last mentioned are really applications of probability sampling where the material is known to be nearly uniform, and where from 50 to 500 selections suffice to establish the required precision in the sample.

"A thorough mixing of the final portion of pulp previous to its division into several samples to be placed in separate packets is indispensable. A large number of rollings on a suitable cloth or paper is the almost universal way to do the final mixing. Rolling, when skill-

fully done, accomplishes the purpose, but the great objection to rolling is that it is tedious and requires both time and patience. If cloth is used it may well have a pebble-grained surface; a paper should have a matte surface. The surface of either cloth or paper is commonly colored black to show the sample more clearly.

"Substitutes for rolling the pulp on cloth or paper have been proposed; the Anaconda sample-mills use cube-mixers and at the School of Mines a small table-riffle answers the purpose. At Anaconda both mills are equipped with eight-inch cube-mixers which are rotated by power slowly enough for the contents to undergo practically the same sort of tumbling which a pulp gets when rolled on a sheet. Cube-mixers have not proved satisfactory in all plants and their use in the State is limited to the Anaconda mills. Students in assaying at the School of Mines have recently mixed their final pulps by pouring them, with shaking to and fro, at least ten times through a table-riffle. As far as can be determined in the course of the regular assaying, the riffle mixing is adequate. It will be explained in considerable detail.

"A riffle-cutter may be used to make either a few or an almost unlimited number of cuts during the division of a sample. Fig. 5 shows an operator pouring a sample through a riffle-cutter which has 26 slots. When the container rests on the edge of the cutter, and the material is merely allowed to flow through the 12 slots which include the width of the stream of ore, there will be six streams flowing into the sample, and the lot may be said to be cut six times for sample. When the operator moves the container across the top of the riffle, say 20 times during the pouring, all of the slots are brought into play and the lot may be cut 20 by 13, or 260, times for sample. The operator might, however, take the ore from the container in a scoop and then pour it through in small portions, shaking each scoopful 20 times across the riffle. If the operator takes a lot of ore in 10 scoopfuls, and pours each across the 26 slots, with 20 to-and-fro motions, he makes, altogether, 10 by 13 by 20, or 2600 cuts, for the sample.

"It is thus seen that a lot of ore is easily cut into a larger number of portions by merely shaking the ore-stream across the riffle. When the two halves of the divided sample have been united the lot of ore has been thoroughly mixed. Both gross and minute inequalities are dispersed throughout the sample by cutting and uniting several times; in other words, the lot has become unusually well mixed.

"I am of the opinion, that, if a sample is shaken 10 times across a riffle, which makes 1000 cuts for sample each time, the pulp will be as well mixed as by rolling 1000 times on a cloth. The riffle-mixing can be done in less than 5 minutes, while the rolling will rarely require less than 15 minutes.

"In order to make an exact test of the mixing that can be done with a riffle I prepared 500 gm. of quartz and 500 gm. of iron ore by grinding each and passing them through a 100-mesh sieve. Each lot was, of course, dry and thoroughly mixed. The iron ore was poured over the quartz in a pan and then the whole was poured through a

12-slot riffle. It was given nearly 100 shakes during the 30 seconds required for the powder to flow from the pan. Two grab-samples of about half-gramme size were taken on a spatula from each half. The two portions were united and the operation repeated. This was done seven times and each time two grab-samples from each half were taken for analysis. The results were as follows:

Quartz, 3.17% iron; iron ore, 43.78% iron; average, 23.48% iron.

Number of mixings	Analysis for iron					Average deviation from 23.48	
	%	%	%	%	%	%	%
1	15.72	32.72	6.04	30.80	21.32	10.44	
2	20.24	20.12	19.24	21.12	20.18	3.30	
3	20.12	21.40	23.40	22.88	21.95	1.51	
4	23.28	23.50	23.40	23.20	23.34	0.15	
5	23.64	23.64	23.44	23.64	23.61	0.13	
6	23.56	23.64	23.44	23.64	23.57	0.11	
7	23.36	23.44	23.52	23.64	23.49	0.09	

"The chemical analyses show that the first mixing had intermixed the iron ore and quartz to a considerable extent, while the second mixing made a nearly uniform product. The third mixing brought practically perfect

ANACONDA SAMPLING-MILL

average composition in streaks, while the fourth mixing doubtless rendered the entire lot homogeneous to within one part in one hundred, which is the accuracy of the chemical analyses, themselves. The 5th, 6th, and 7th mixings changed the composition in an almost inappreciable degree. The chemical determination of iron was chosen because it could be done more easily and with greater precision than almost any other determination or assay.

"Material which yields identical composition on haphazard samples fulfills the test of uniformity; this test is one of mixing rather than anything else."

It is needless to add that, when a lot of ore of the required fineness is passed over a riffle so as to make many hundred or a few thousand divisions, it splits the lot into two halves which are duplicates of each other. The repeated splitting of one of the halves thus quickly reduces

FIG. 5. STAND RIFFLE-CUTTER USED AT MONTANA SCHOOL OF MINES

the size of the lot to any smaller quantity that may be desired for a sample. Quoting further:

"Whenever the riffle-cutter has been tested under proper conditions it has given admirable results; it is, accordingly, strongly recommended wherever it can be used. The prospector and miner will find riffles both cheap and handy. Riffles can be used wherever cone-and-quarter sampling or split-shovel sampling is now used. The utmost use of riffles will tend toward uniformity, low cost, rapidity, and the greatest possible precision in sampling.

"PROBABILITY SAMPLING WITH MECHANICAL CUTTERS. There is no doubt but that the results of sampling must follow some probability curve, mathematically determinable from the factors involved; the engineer makes certain that the curve shall be of the shape indicated in Fig. 6. The curve means that, depending on the number

of divisions or cuttings for sample, the probable result will lie within the extremely narrow vertical portion of the blackened area. On this basis, if the ore is repeatedly crushed between divisions so as to circumvent the influence of large single particles, the degree of accuracy is not obtained, although the crushing and dividing is repeated as many times as necessary to sufficiently reduce the size of the sample.

"The law of averages and the theory of probability demonstrate that if either single pieces or small portions of a large lot are chosen at random the composition of the selected portion finally will approach, as a limiting condition, the composition of the entire lot. Obviously, if one selects the entire lot, the sample and lot become identical. However, it is not necessary to take the entire lot, for by mixing and taking a sufficient number of single particles, or by making enough cuttings, or by a combination of mixing and dividing, it is possible to take not more than one-fifth, one-tenth, or even one-twentieth of the lot and still get a truly representative sample. Shovel-sampling, split-shovel sampling, rifle-sampling, and the use of all types of mechanical cutters involve more or less of the probability principle.

"To make the probability overwhelmingly on the side of precision, a questionable number of divisions is not made, but thousands of divisions, each portion containing thousands of particles, are made. Furthermore, the possibility of large pieces influencing the results is precluded, and any influence that can interfere with absolutely random division is avoided. Thus any influence which tends to select according to size, weight, density, color, hardness, porosity, or any other imaginable property is eliminated.

"In actual sampling the sequence of crushing and cutting is commonly performed from six to ten times. Each portion of the thousand or more selections made by one machine contains millions of particles and the final result has every assurance of correctness. The proof of this consists, not in analyzing the entire lot, which, as already stated, is impossible, but in repeating the process, in getting duplicate samples, or by sampling by an entirely different method.

"If a lot of ore weighing 50 tons requires 60 minutes to go through a mill whose mechanical cutters are taking out one-fifth at the rate of 60 cuts per minute and are in series of four, the first cutter will make 3600 selections and take out 10 tons containing millions of particles. After crushing, the second cutter will make its 3600 selections from the first sample and take out its two tons containing again millions of particles. Then the third cutter will divide the two-ton lot, making its 3600 selections and taking out 800 lb. containing again some millions of particles. The last cutter will divide the 800 lb. and with its 3600 selections take out 160 lb. in another sample likewise containing millions of particles. The process of crushing and dividing is then continued with suitable machines, usually in the bucking-room, until the final analysts' packets, each containing millions of par-

ticles, represents the original lot with the same precision as that of any previous larger selection or sample."

Probability sampling depends on certain other factors besides the number of cuts for accurate sampling; three of the most important are: (1) that the cutter-openings shall be large enough to pass the largest pieces without discrimination; (2) that none of the pieces shall be large enough to alter the results by falling individually in either sample or reject; and (3) that no valuable mineral shall be in such single rich aggregates as to affect the results when the piece containing the aggregate falls in

FIG. 6. PROBABILITY CURVE FOR DISTRIBUTION OF SAMPLING-RESULTS

either sample or reject. These conditions have been considered at length in the more important articles on sampling.

EQUIPMENT OF MONTANA SAMPLING-MILLS. The Montana sampling-mills use the customary machinery for transferring ore from the railroad-cars or receiving-bins to the various places in the mill, and for finally disposing of it. Steel-pan conveyors, shaking-grizzly feeders, shaking troughs, bucket-elevators, belt-conveyors, and trolley-buckets are in use at the several mills. Crushing and grinding is done by gyratory breakers, jaw-crushers, rolls, bell-grinders, disc-grinders, and on bucking-boards. Sample-cutting is done with the Brunton vibratory cutter, the Brunton oscillatory cutter, the Vezin cutter, the East Butte cutter, and the Snyder cutter (at the State School of Mines) for mechanical work, and with split shovels, pipes, and stand and table-riffles for hand-sampling.

The Washoe sampler at Butte cost \$150,000; it is constructed of steel and concrete and is capable of sampling

ANACONDA SAMPLING-MILL

500 tons in eight hours. Sample-cutting is done by Brunton oscillatory cutters. The mill will sample the usual lot of 50 tons of ore in about 25 minutes, and can then be thoroughly cleaned and blown out with compressed air during the few minutes required to dump the next car-load of ore into the receiving bin. The facilities for shifting cars, weighing, storing lot and reserve-samples, and doing the bucking-room work promptly and accurately are superior to those of any other mill in the district. Crushing is done with a 20 by 10-in. jaw-crusher and 16 by 36, 14 by 30, and 12 by 24-in. rolls. The Brunton oscillatory sample-cutters have sample openings 7 by 10.5, 6 by 8, 4.5 by 6.75, and 3.5 by 5 in. and make 40,

28, 63, and 68 cuts, respectively, per minute. The bucking-room is equipped with split shovels, pipe-samplers, stand and table-riffles, bell and disc-grinders, bucking-board, and electric cabinet-dryer.

The East Butte sample-mill is a frame structure equipped with 12 by 24-in. crusher and 16 by 36, 10 by 24, and 9 by 9-in. rolls. The East Butte type of sample-cutter is used; the sample-openings are 8 by 12, 6 by 7.75, and 4.5 by 5.5 in., respectively. The rates of cutting are 28, 26, and 16 per minute. The mill has an unusually large stand-riffle cutter. In the bucking-room are individual units comprising steam-table and cabinet, small crusher, grinder, disc-grinder, and bucking-board. Samples are

FIG. 7. PIPE-SAMPLING OF FLOTATION CONCENTRATE

split with riffles and pulps are mixed by hand-rolling on a cloth. The most noteworthy feature of the mill is the use of drum-mixers above the second and third sample-cutters; they work smoothly and give their respective cutters better mixed and more uniform feed than is usual in the other mills.

The No. 1 mill at the American Smelting & Refining Co.'s plant at East Helena is served entirely by belt-conveyors. It is a steel and concrete mill capable of sampling 400 to 500 tons in an eight-hour shift. The precision of sampling at this mill should excel that of any other Montana plant since all material is customarily ground to pass a $\frac{3}{8}$ -mesh screen before going to the sample-cutters. The fine grinding also assures time enough in sampling so that a 50-ton lot of ore almost inevitably gets 3000 sample-cuts by each of the four Vezins. The mill is equipped with No. 5 and No. 4 McCully gyratory crushers and two 16 by 36, and 12 by 12-in. rolls. The sample-openings in the Vezin cutters are 14 by 20 and 3 by 20 inches in the first, and 7 by 10 and 1.5 by 10 inches in the three succeeding cutters, while the samples are cut at the rate of 30, 34, 40, and 40 per-minute. The bucking-room has ample equipment. Cone-and-quarter sampling is extensively used both on a large steel floor and in the bucking-room.

The Anaconda sampling-mill has a capacity of 2000 tons in eight hours. It is a frame structure piped for automatic sprinkling in case of fire. Most of the ore sampled is the low-grade copper from the company's mines at Butte. The mill is built and operated as two duplicate, but wholly independent, twin units; the equipment of one half only is described. Crushing is done by a 12 by 24 and an 8 by 18-in. crusher, and by 15 by 40 and 14 by 26-in. rolls. Sample-cutting is done by Brunton oscillatory cutters whose sample openings are 11 by 15, 7 by 11, 5.5 by 8, and 3.5 by 5 in., respectively. The number of cuts for sample are 24, 36, 44, and 76, in the same order.

The bucking-room at the Anaconda sampler is divided into twin units. It has steam-cabinet dryer, bell-grinders, disc-grinders, power-sieves, bucking-boards, cube pulp-mixers, and stand and table-riffles.

The sampling-mills in Montana do excellent work on low and medium grade ores. It is customary to clean the mills with compressed air between lots and all of the sample-cutting devices are capable of doing work of the required precision. Roll practice has not yet advanced to the recent idea of full and uniform feed, while corrugation of the shells sometimes exists to an undesirable extent. The mills are doubtless clean enough for sampling but are not sufficiently free from dust to meet approved hygienic standards. The precision of moisture-sampling appears to be capable of improvement; when equipment for handling dust is more generally used, it may be that 'air-conditioning' will come into vogue and there will be maintained inside the mill a 'climate' which will neither take nor give moisture to the sample as it is being cut and crushed during its progress through the mill.

Pumping on the Rand

G. H. Beatty describes the general arrangement of a pump-station on the 2500-ft. level at the North Deep shaft of the Randfontein mines on the Rand. The plant consists of four units of the well-known Sulzer type, each designed to deliver 84,000 gal. per hour against a head of 2500 ft. Each pumping-set consists of one five-stage right-hand suction-pump and one eight-stage left-hand pressure-pump. The pumps are coupled in series, and driven by an electric motor arranged between the pumps on a cast-iron base-plate common to pumps and motors. The motors are 1750 hp., and rotate at 1470 r.p.m. Delivery is through three 10-in. rising mains taken from the pump-station to the shaft at an angle of 50°, and thence to the surface. The mains are supported by ducks' feet on box-girders placed across bearers in the shaft, and are further supported at intervals in the shaft. Each main is provided with an expansion-joint placed half way up the column.

It does not seem to be the usual practice to have expansion-joints in water-columns, but they have some advantages. In this case the weight of metal in the columns is 270 tons, and the expansion-joints permit of two permanent points of support unaffected by expansion and contraction. There is little or no variation in the temperature of the mine-water, and under running conditions there is no expansion or contraction, provided the columns are always in use. But the water temperature is 72°F., and the shaft temperature averages about 52°F., so that when pumping through a column ceases, contraction commences. Loss in temperature of a column full of water is slow under the prevailing conditions, but if the column is drained the drop is rapid, and contraction correspondingly so. If it is necessary to put a column out of commission it is advisable to slack off the intermediate supports and allow its full weight to bear on the duck's foot and expansion-joint supports, otherwise strains are set up and trouble in the column follows. The North Deep shaft was commenced in September 1917. The permanent headgear was erected at once, and good progress made in the shaft. The high angle of dip of the strata was not conducive to record-breaking, and the 18th level-station (2500 ft. below the collar) was cut in March 1919. Shaft-sinking was stopped for two months owing to a delay in timber coming forward, and advantage was taken of the delay to install the rising-mains and cables, and lower the pumps and fittings to the chamber. All the pump-gear, motors, pipe-fittings, etc., were lowered to the pump-station in less than 49 hours by means of a specially designed cage slung below the skip. The cage was fitted with rails to take trolley loaded with the material.

The trolleys were run out of the cage over a drop-set and directly into the chamber, and unloaded by means of a traveling-crane which runs the full length of the chamber. The pumping-plant has now been in operation for five months. The water pumped during July and August amounted to 215,300,000 gallons.

The Mechanism of the Surface Phenomena of Flotation

By Irving Langmuir

*Notwithstanding the importance that the flotation process has assumed in the separation of ores, there has been comparatively little progress in the development of the underlying theory. It is recognized that the process depends on the formation of thin oil-films on the particles of ore and that owing to the difficulty with which these particles are then wet by water they become readily attached to the air-bubbles and are thus carried to the surface. As far as I know, however, no really satisfactory theory of these phenomena has been proposed. The remarkably selective action of some oils on certain ores and the effects produced by small amounts of acids and other substances are very imperfectly understood.

The object of this paper is not to offer a new theory of flotation, but rather to call attention to a theory of adsorption and surface-tension that greatly aids in understanding these phenomena and that therefore should prove useful in developing any comprehensive theory. Some simple experiments will be described showing that the new viewpoint is applicable to flotation processes.

The surface phenomena of flotation may be divided roughly into three classes: the formation and properties of the froth; the oiling of the solid particles; and the adhesion of the oiled particles to the bubbles of the froth. The formation of the froth depends on the existence of a film of oil or other substance at the boundary between the air and water phases. The oiling of the solid particles involves the formation of a similar film at the surface of the solid. The adhesion of the particles to the bubbles depends primarily on the ease with which oily water wets the oily solid and this in turn is measured by the angle of contact between these oiled liquid and solid surfaces. The formation of the oil-films on the surfaces of the water and the solid particles is a typical case of adsorption, so that an understanding of the fundamental phenomena of flotation requires a knowledge of the nature of adsorption.

For several years I have been engaged in a study of high-vacuum phenomena, especially the effects produced when various metals are heated in gases at very low pressures. In some cases the rate of disappearance of the gas was measured, while in others the electron emission from the heated metal was observed. In the course of this work it was frequently found that adsorbed films of extraordinary stability were formed on the surface of the metal. The evidence from a large number of such experiments indicated clearly that these stable films consisted of a single layer of atoms chemically combined with the underlying atoms of the solid. The adsorbed atoms were chemically saturated, but the atoms in the surface of the metal were not saturated by their com-

bination with the adsorbed atoms and therefore remained firmly held by the next underlying layer of metal atoms. This viewpoint was based to a large extent on the work of Braggs on crystal structure.

The atoms in the stable films are clearly held to the surface by direct chemical union of the primary valence type, like that holding oxygen to carbon in carbon di-oxide. Further investigation showed that in some other cases of adsorption, such as that of nitrogen or argon by charcoal, etc., the forces involved, although no less chemical than the others, were of the type represented by secondary valence such as that holding water of crystallization, or ammonia in complex ammonia derivatives.

A further extension of this theory led to the view that no fundamental distinctions should be drawn between the so-called physical phenomena and those recognized as chemical. Thus condensation of vapors, crystallization, surface-tension, adsorption, etc., are manifestations of forces of the same kind as those involved in the formation of chemical compounds.¹

From this viewpoint, the forces involved in the adsorption of organic substances with large molecules do not originate from the molecule as a whole, but rather films in general should be one molecule in thickness. Lord Rayleigh in 1899 (*Phil. Mag.* 48, 331 (1899)) observed that a film of olive-oil just thick enough to lower appreciably the surface-tension of water had a thickness of 1.0×10^{-7} cm. He stated: "Now this is only a moderate multiple of the supposed diameter of the gaseous molecule, and perhaps scarcely exceeds at all the diameter to be attributed to a molecule of oil. It is obvious, therefore, that the present phenomena lie entirely outside the scope of a theory such as Laplace's in which matter is regarded as continuous and that an explanation requires a direct consideration of molecules. If we begin by supposing the number of molecules of oil upon a water surface to be small enough, not only will every molecule be able to approach the water as closely as it desires, but any repulsion between molecules will have exhausted itself. Under these conditions there is nothing to oppose the contraction of the surface—the tension is the same as that of pure water."

If the molecules "behave like smooth rigid spheres of

¹The evidence for these conclusions is given in the following papers by the writer: 'Chemical Reactions at Low Pressures', *Jour. Amer. Chem. Soc.*, 37, 1139 (1915); 'The Constitution and Fundamental Properties of Solids', *Jour. Amer. Chem. Soc.*, 38, 2221 (1916); and 'The Adsorption of Gases on Plane Surfaces of Glass, Mica, and Platinum', *Jour. Amer. Chem. Soc.*, 40, 1361 (1918). A review of this work is given by Wm. C. McC. Lewis in his recent 'System of Physical Chemistry', Longmans, Green & Co., 1918, Vol. I, pp. 461-474.

*Abstract of a paper read before the Faraday Society on July 14, 1919.

gaseous theory, no forces will be called into play until they are closely packed. According to this view the tension would remain constant up to the point where a double layer commences to form. The actual course of the curve of tension deviates somewhat widely from the above description, but perhaps not more than could be explained by heterogeneity of the oil, whereby some molecules would mount more easily than others, or by reference to the molecular motions which cannot be entirely ignored. If we accept this view as substantially true we conclude that the first drop in tension corresponds to a layer one molecule thick, and that the diameter of the molecule of oil is about 1.0×10^{-7} cm."

By a similar method Devaux (Ann. Report Smithsonian Inst., Washington (1913), 261) concludes that the diameter of the molecule of triolein is 11.3×10^{-8} cm. if the molecule be assumed spherical in shape.

According to the present theory, however, molecules should not be regarded as spheres, since such a supposition is not consistent with the chemical nature of the forces. The spreading of an oil on the surface of water is therefore due to an attraction between the water and some active group in the oil molecule. If the molecule as a whole had an affinity for water it would render it soluble in water. It is known that the presence of $-COOH$, $=CO$, or $-OH$ groups in an organic molecule increases the solubility in water while the hydrocarbon chain decreases it. On the other hand, hydrocarbons are soluble in each other. When an oil containing the carboxyl group is placed on water these active groups combine with the water, while the hydrocarbon chains remain combined with each other by secondary valence forces. On an unlimited surface the oil thus spreads until all the $-COO-$ groups have come into contact with the water, forming a mono-molecular film. A pure paraffin-oil, since it contains no active groups, does not spread on water.

By measuring the greatest area of water that can be completely covered by a small weighed amount of oil, it is possible to determine the cross-sections and lengths of the molecules. The thickness of the oil-film gives the length of the molecule measured vertically, while the area covered by each molecule gives its cross-section. Results obtained this way show that the molecules in oil-films are not even approximately spherical. This is shown by the data of Table I.

Thus the molecules of the fatty acids from palmitic to cerotic are all of the same section, but their length increases in proportion to the length of the hydrocarbon chain. Tristearine has a cross-section three times that of stearic acid, but the length of the molecule is the same. The areas covered by the oils or fats are thus proportional to the number of active groups present. The molecule of cetyl palmitate is nearly ten times as long as it is wide (\sqrt{a}), while the molecule of triricinolein (castor oil) has a length only about one-third of its

Table I			
Substance	Cross-section a , and length l of molecules

Castor oil, $[C_{17}H_{33}(OH)COO]_3C_3H_5$..	290	17.0	5.5

width. The results show that these differences of shape are strictly in accordance with the theory of the chemical nature of the phenomena.²

The same theory has been applied to surface-tension phenomena in general. According to this theory the molecules of organic liquids arrange themselves in the surface layer in such a way that their active portions are drawn inward, leaving the least active portion of the molecule to form the surface. Surface-tension is a measure of the potential energy of the stray field extending out from the surface layer of atoms. The molecules in the surface layer arrange themselves so that this potential energy is a minimum. The surface-energy of a liquid is thus not a property of the molecule as a whole, but depends only on the *least active portions of the molecules* and on the manner in which these are able to arrange themselves in the surface layer.

In liquid hydrocarbons of the paraffin series the methyl groups at the ends of the hydrocarbon chains form the surface layer. The surface is thus the same no matter how long the chain may be. As a matter of fact, the surface-energy³ of all the hydrocarbons from hexane to molten paraffin is substantially constant, namely 46 to 50 ergs per square centimetre, although the molecular weights differ very greatly.

If now we consider the alcohols, CH_3OH , C_2H_5OH , etc., we find that their surface energies are practically identical with those of the hydrocarbons. The reason is that the surface layer in both cases consists of CH_3 groups. With such substances as CH_3NO_2 , CH_3I the surface energy is much greater than that of the hydrocarbons. This is partly due to the fact that the large volume of

²The experimental and theoretical work underlying the above statements has been published in the following papers by the writer: 'Surface Tension Phenomena', Met. Chem. Eng., 15, 468 (1916); 'The Shapes of Group Molecules Forming the Surfaces of Liquids', Proc. Nat. Acad. Sciences, 3, 251 (1917); 'The Constitution and Fundamental Properties of Liquids', Jour. Amer. Chem. Soc., 39, 1848 (1917). A short summary of some of this work has been given by Wm. C. McC. Lewis, 'Physical Chemistry', Vol. I, p. 474.

³The total surface energy γ_0 is related to the surface-tension γ by the equation $\gamma_0 = \gamma - T (d\gamma/dT)$ where T is the absolute temperature.

the NO_2 or I forces the CH groups apart and increases the surface energy. It is apparent that considerations of this kind must be of fundamental importance in connection with the theory of the flotation process. Before much progress in this direction can be made, however, it is necessary to develop experimental methods for the investigation of oil-films on solid bodies. With this end in view I have undertaken some simple experiments.

EXPERIMENTS

A study was first made of the properties of cleaned and oiled glass surfaces. It was especially desired to find how much oil must be present on a glass surface to alter materially its properties.

Microscope slides were washed with soap and water, were heated in a mixture of concentrated sulphuric acid and chromic oxide, and were finally washed in running tap water and dried over a Bunsen-burner flame. During this whole treatment they were held in a pair of forceps. This method of cleaning proved to be much more thorough than any other method tried.

When a drop of clean water is placed on a slide cleaned in this way the water wets the glass readily, and when the slide is inclined the surplus water runs to one end, leaving a thin film of water over the whole surface of the glass. Another indication of the cleanliness of the surface is obtained by dipping the slide into a clean surface of water onto which a small amount of talc powder has been dusted. The talc particles are not repelled from the glass surface if it is clean, but very small amounts of grease can be detected by the motion of the talc particles produced by the spreading of an oil-film on the surface of the water. This test for the cleanliness of a surface will be referred to as the talc test.

Another characteristic of a thoroughly cleaned glass surface is the extraordinary friction observed when the glass is rubbed with another clean piece of glass or platinum. Lord Rayleigh⁴ has recently called attention to this fact and pointed out its significance in connection with the theory of lubrication. It is also interesting to note that Faraday in his 'Experimental Researches' (paragraph 369) mentions the "peculiar friction" observed when a platinum rod was rubbed over a surface of a platinum plate which had been thoroughly cleaned by making it cathode in electrolysis or by heating it in concentrated sulphuric acid.

In order to study this effect quantitatively, some small glass sliders ranging from 0.2 to 1.0 gramme in weight were made by bending glass rods in the form of a horseshoe and well rounding the ends. The two arms of the horseshoe were then arched in a plane perpendicular to the original plane of the horseshoe, so that when the slider was laid on a flat surface it touched in three definite points. If one of these sliders was placed on a clean slide, it was found that the slide could be tilted usually to an angle of 70° from the horizontal, often 75° , and in some cases 90° or even 92° , before it would begin to slide. Of course, before beginning this test it is essential to

clean the slider by the method already given. If the slider was forced over the surface of the slide a squeaking noise was always heard if the glass was clean and the surface of the glass was scratched perceptibly in the process. It was found that much more consistent results were obtained by means of a pair of forceps. The angle was measured at which the slider would just stop moving after being set in motion by the forceps. The sliding-angle thus found varied between 50° and 60° for different samples of glass cleaned by the method described. On standing in the air for a short time the surface becomes slightly contaminated, so that the sliding-angle decreases. Thus, after three minutes the angle is 45° , after 20 minutes 40° , after two hours 22° . This contamination is also shown by the talc test. The actual size of the slider used seemed to be without effect on the results.

In order to put a mono-molecular film of oil on a glass surface the following method was adopted. The surface of water in a long narrow tray was cleaned by scraping with a strip of paper extending across the tray. A very small quantity of oleic acid was placed on the water at one end of the tray and the spreading of the film was made visible by traces of talc powder. By adding the oil in very small portions the surface was finally saturated with oil without leaving any globules of oleic acid except at the end of the tray at which they had been added. Previous work had shown that an oleic-acid film formed in this way has a thickness of 22×10^{-8} cm. and consists of a single layer of molecules each occupying an area about 24×10^{-16} sq. cm., the spacing thus being the same as that of stearic acid and the other saturated fatty acids. The cleaned slide was then dipped edgewise into the water covered by this film and slowly withdrawn. As the slide was raised it remained at first wetted by the water and the film of oil spread itself over the newly formed water surface. The motion of small particles of talc showed that the oil-film moved upward at the same rate as the slide was raised, so that there was no concentration of oil on to the surface of the glass. When a clean slide is originally dipped into the water the talc particles close to the surface do not move either toward or away from the slide. This indicates that no oil goes on to the glass surface while this is being lowered into the water. This remarkable fact is confirmed by removing the oil-film from the surface of the water by scraping and blowing before withdrawing the slide from the water. If the slide is then dried at ordinary temperature it is found both by the talc test and the friction test that the surface is still entirely free from oil. If, on the other hand, the slide has been raised from the surface saturated with oil and is held in a vertical position the water-film gradually moves down and the oil-film on it comes into contact with the glass. The same result may also be obtained by holding the slide in a horizontal position and allowing the water to evaporate. In this way the glass surface is covered with a film of oil of the same thickness as that originally present on the surface of the water.

⁴Phil. Mag., 35, 157 (1918).

A slide treated in this way appears just as clean as before, but if dipped in clean water it is found that the water no longer adheres to it but gradually runs off, as from a greasy surface. The tale test gives a rather slight indication of contamination, but if the slide is raised and lowered repeatedly in pure water, or is passed several times through a gentle stream of running water, it soon loses its ability to contaminate water. The friction test gives a sliding-angle of about 60° to 10°, whether or not the surface has been washed by clean water before drying.

In other experiments the film of oleic acid was allowed to expand on the water surface until the surface-tension was nearly that of pure water. The thickness of such a film (see Table I) is 11×10^{-8} cm., and the area covered per molecule is 48×10^{-16} sq. cm. A glass slide oiled by dipping and slowly withdrawing from this oiled water and drying in a horizontal position gave sliding-angles ranging from 6° to 20°. The results were rather erratic and indicated that the oil was not uniformly distributed over the slide, but was concentrated somewhat on those portions which were the last to dry. If the slide was allowed to dry in a vertical position, the upper part of the slide was found entirely free from oil, while the rest of the slide was uniformly covered.

Freshly split mica (biotite) is very readily wetted by water and by paraffin-oil, but oleic acid and molten stearic acid form globules. These acids, however, leave the surface greasy even after the globules have been removed.

A smooth piece of platinum foil (1½ by 3 inches) was polished with sea-sand and ignited to a red heat. It was readily wet by water. As in the case of glass and mica, platinum does not become contaminated when dipped into oiled water, but only when it is drawn out and dried. Clean platinum gives a sliding angle of 35° with a platinum slider, and 30° with a glass slider. After dipping once in water saturated with oleic acid and drying, the sliding-angle with both glass and platinum sliders was 14°.

Fresh cleavage-surfaces or fractures of calcite, sphalerite, galena, pyrite, and magnetite were all readily wetted by water or paraffin-oil, and in each case the paraffin-oil was readily displaceable by water. The clean surfaces all became greasy by dipping into water saturated by oleic acid, and in every case it was impossible to remove the greasiness by repeatedly passing through a stream of water. On cleavage-surfaces of calcite and galena rough qualitative observations showed that there was a peculiar friction, as in the case of glass.

MEASUREMENT OF CONTACT-ANGLES OF DROPS OF WATER ON OILED SURFACES

Simple observation showed that drops of water behaved rather differently on various solid surfaces that had been dipped into water saturated by oleic acid.

Drops of water placed on oiled glass flattened out to a layer about 2 mm. thick. By tilting the glass the drop would advance over the surface at the lower edge, forming a rather large angle of contact, while at the rear

edge the water would recede from the glass rather slowly, and the angle of contact was much less than at the advancing edge. The moving drop was usually rather irregular in outline. On mica the depth of the drop is less than on glass, and the drops are more irregular in shape after moving over the surface. With platinum the drops of water become thicker and more symmetrical in shape, while on galena they show a still greater thickness and regularity.

To obtain more definite information, drops of water ranging from 0.7 to about 1.22 cc. in volume were placed on oiled surfaces and their heights measured by a vernier attached to a fine point brought into contact with the drop and subsequently with the solid surface on which the drop had rested. The results are given in Table III. The figures in the columns marked *h* represent the depths of the drops in millimetres, while θ is the average contact-angle as calculated from the equation

(1) $h = 2\sqrt{2} \sin(\frac{1}{2}\theta)$

where *a* is given by

(2) $a = 2\sqrt{\gamma/(g\rho)}$

Here γ is the surface-tension; *g* the acceleration of gravity, and ρ the density of water. This equation is accurate only for large drops. Those actually used ranged from 1.4 to 2.5 cm. in diameter, and a further increase in the size of the drop did not appreciably alter the value of *h*.

In each case the oily surface was prepared by dipping a very small amount of cleaned (or cleavage) surface into water saturated with oleic acid, and drying at low temperature. The water drop was then placed on the surface and this was shaken and sometimes tilted slightly, so that the drop reached a stable shape. The results given are the averages of several observations. In most cases the individual observations on different drops agreed within about 0.1 mm. in the value of *h*.

The measurements of the column marked *I* were made with drops of clean water. In many cases the drops are slightly contaminated by oil from the solid surface. In every case a very small amount of talc was dusted on to the drop after measuring it, and by gently blowing on it the contaminated surface was forced to one side where its

Table III
Height and Contact-Angles of Water Drops on Surfaces Covered by Mono-molecular Films of Oleic Acid

Solid	I. Clean water		II. Water saturated with oleic acid	
	<i>h</i> mm.	θ	<i>h</i>	θ
Mica	0.9	18°	0.9	24°
Quartz	1.2±	31°±
Glass	2.1	45°	1.5	42°
Platinum	2.9	65°	2.45	72°
Calcite	3.1	70°	2.75	82°
Sphalerite	3.6	82°	3.0	92°
Galena	3.7	86°	3.35	106°

area could be estimated. The areas were always less than about 60 or 70% of the whole surface, so that the surface-tension of the drop could not have been appreciably affected. This conclusion was checked in some cases by re-

peating the measurements after the surface had been washed by passing through a stream of running water until drops placed on the surface were no longer contaminated. In each case (except mica) the results remained unaltered. In calculating the angles of contact, δ in the above equation (2) was placed equal to 72.8, so that equation (1) became

$$(3) \quad h = 0.456 \sin (\frac{1}{2}\theta)$$

The measurements given in the second column of Table III were made after the drops of water had been touched by a wire dipped in oleic acid. In this case δ of equation (2) was taken to be 42.8, so that the coefficient of equation (3) was 0.418 instead of 0.456.

DISCUSSION OF EXPERIMENTAL RESULTS

The experiments have shown clearly that oil-films of molecular thickness are sufficient to alter radically the surfaces of solids. This is shown not only by the lubricating properties of these films but also by the contact-angles made by drops of water.

The properties of these mono-molecular films as measured by the contact-angles depends apparently as much on the character of the underlying solid as upon the nature of the oil. Thus the minerals galena and sphalerite give much larger contact-angles when contaminated by oleic acid than those obtained with glass or quartz under similar conditions. This result seems to be inconsistent with the theory of surface-tension discussed in the early part of this paper, according to which the surface-tension depends only on the nature of and arrangement of the atoms forming the actual surface. From this viewpoint, we would be led to believe that the upper surface of oil-films on solid bodies should in every case consist of CH_2 or CH_3 groups, and thus the properties of all the films should be similar. However, there is an important distinction between the case of an oil-film covered by a water drop and the surface layer of a pure organic liquid. The water drop on the film tends to draw the active groups to itself. In the case of oleic acid there are two active groups in the molecule, namely, the carboxyl and the double bond. It is probable that in some cases both of these are rather firmly held by the underlying solid, while in others only the carboxyl group is so held and the double bond is free to come in contact with water. Thus on galena we may assume that both active groups are held by the solid so that the water has only a little more tendency to spread on the oiled surface than on solid paraffin. With glass, on the other hand, some of the active groups may be brought to the upper surface by contact with water so that the water spreads much more easily than over paraffin. This theory readily explains the marked difference between the contact-angle of an advancing and receding surface on glass contaminated by oleic acid.

Another factor which must be taken into account is that the spacing of the molecules in oil-films on solids must be determined primarily by the surface lattice of the solid, whereas with films on liquids the molecules are able to arrange themselves largely without reference to the

underlying liquid. As a result the films on solids are ordinarily not in stable equilibrium; many molecules are crowded into spaces too small for them, while others may occupy unnecessarily large areas. As a matter of fact, in all the experimental work with films on the solids the results were much more irregular and depended much more on slight differences in the previous history of the film than was the case with films on liquids.

The peculiar property of mica in giving such a small sliding-angle even when cleaned indicates that the surface is covered with water molecules with their hydrogen atoms thoroughly saturated and turned outward to form the surface layer. The great ease with which mica cleaves and the readiness with which oil-films can be washed off and water can spread on these oil-films is also a result of the small residual field of force extending out from these surface hydrogen atoms.

APPLICATION TO THE THEORY OF FLOTATION

The formation of froth depends on the presence of substances that can form a stable mono-molecular film over the surface of each bubble. In order that froth may readily form it seems to be desirable to have present a soluble substance having a strong tendency to be adsorbed on the surface of the liquid. For example, a small amount of acetic acid added to water produces a rather unstable froth. As we go to the higher fatty acids, for example, valeric acid, the tendency to form a froth is much increased. On the other hand, oleic acid does not readily produce a froth unless it is rendered soluble in water, as, for example, by forming soap by the addition of sodium hydroxide. Oil of pine-tar, so often used as a frothing-agent, contains soluble substances that probably act in this way. The presence of alkalies in flotation is to be avoided probably because the hydroxyl ion tends to draw the carboxyl group of the fatty acid to itself rather than to allow it to attach itself to the solid particles.

The particular properties of different kinds of oils must be made the subject of further careful study. The presence of small amounts of acid and substances that become adsorbed on the solid surfaces or attach themselves to the oil-films would be expected to alter the results materially. This subject is, of course, a very large one, and will necessitate much experimental work before it becomes well understood.

The tendency of the particles to attach themselves to the bubbles of the froth is measured by the contact-angle formed between the oily surface of the bubble and the contaminated surface of the solid. For the case where oleic acid forms both films the data given in the second column of Table III are applicable. The results indicate that the selective action by which substances like galena are separated from quartz and calcite is dependent upon the contact-angle formed by the oiled surfaces rather than by any selective tendency for the oil to be taken up by some minerals more than by others.

THREE dredges formerly operated in Alaska by the Yukon Gold Co. have been moved to the Malay peninsula where they are now ready to commence dredging for tin.

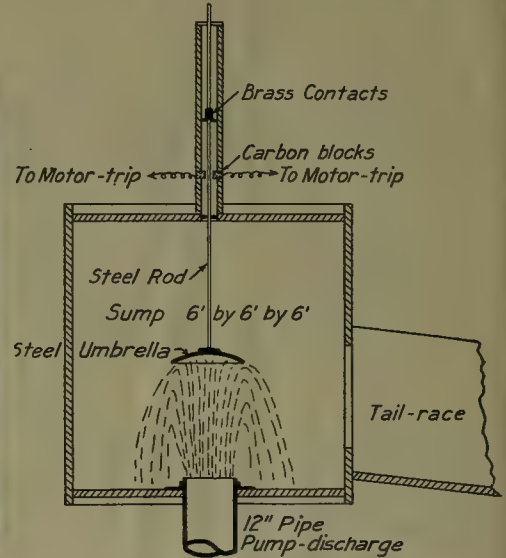

Pump for Elevating Tailing

This device was put into use in June 1916 for the purpose of elevating the tailing from the jigs for distribution on the tailing-dump at the West mill of the Bunker Hill & Sullivan company at Kellogg, Idaho.

It consists of a 12 by 24-in. Byron Jackson centrif-

ugal pump, so that when the fountain of water from the pump lowers to a dangerous point, these contacts rest upon the carbon blocks, completing the circuit through the trip at the motor, and stop the motor.

Provision is made for automatically taking care of the feed to the pump by gravity flow when the pump is not

ugal pump of the 1915 design, direct-connected to a 75-hp. Westinghouse motor running 500 r.p.m. and consuming 61.6 hp. under full load. The pump handles 600 tons of tailing per 24 hours, ranging in size from $1\frac{1}{4}$ in. to 20-mesh. It also handles 4500 gal. of water per minute and discharges at an elevation of 25 ft. from the centre of the intake.

The pump discharges vertically into a sump, 6 by 6 by 6 ft., the pulp flowing out of this sump over a weir into the tailing-flume, which is 32 in. wide and three feet high. The flume has white-iron riffles six inches high set on edge across the flume every two feet for a distance of 200 ft., forming a bed of tailing in the bottom for a wearing-surface. The remainder of the flume is protected in the same manner with 6 by 6-in. blocks for riffles.

A white-iron runner in the pump lasts about 30 days, a white-iron follower about six months, and a liner made of car-wheel iron lasts a little over a year. One casing has been used in three years.

In order to protect the pump when, for any cause, such as the runner wearing out, the volume of water discharged is insufficient to carry the tailing away, thus filling the discharge-pipe with tailing, a device shown in the accompanying sketch was invented by Edward Hearing, the mill-foreman. It consists of a steel 'umbrella' upon which the stream from the pump impinges. To this umbrella a rod is attached which extends upward through a box in which are placed two carbon blocks forming the electrodes of a current passing through a no-voltage release, or trip, on the motor connected to the pump. At a proper place upon the rod, two brass contact-points are

running and also during the five-hour period required to change the runner in the pump.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

CRIPPLE CREEK MINES PASS DIVIDENDS.

CRIPPLE CREEK.—The Portland Gold Mining Co. has announced temporary discontinuance of dividends, "until mining conditions improve and the efficiency of miners increases". The statement to the stockholders says that the mine and mill are in splendid condition "but mining costs are high and \$2 ore with a profit of \$1 is not worth while". The company has paid dividends for 26 years; 17 of these were regular distributions, and the total to date is \$11,692,080. The last dividend of two cents per share was paid on October 20. No mining company in the district is now on a dividend-paying basis.

GEORGETOWN.—Operations have been resumed on the Josephine in Grizzly gulch, where a new shaft is being sunk near the tunnel portal to prove-up the vein. If ore is proved continuous a new tunnel will be started to open the shoot at much greater depth. The Denhigh corporation has installed a compressor, and winter operations will be carried on by machine-drills.

The Georgetown tunnel is reported showing porphyry and quartz in the heading with low silver value and a trace of gold. The tunnel is making water, indicating the proximity of a vein.

HOT SULPHUR SPRINGS.—The Electro Copper Co., owning 160 acres in the Harmony Creek district in Routt and Eagle counties, 44 miles from here, is developing a good copper prospect. Samples from the blanket formation opened by tunnel and shafts, all in ore, range from 5½ to as high as 37% copper. The company has purchased machinery and will install an electrolytic plant. The Moffat road traverses the property, a townsite has been surveyed, and camp established.

LAKE CITY.—The Standard Mines Development Co. has awarded a contract for the extension of the lower tunnel on the Little Chief to cut at depth an ore-shoot in an upper tunnel that is producing silver-lead ore running as high as \$100 per ton. Machinery and equipment for the Colorado Consolidated property at Sherman has been delivered. A new power-plant is under construction and a mill is planned for the spring of next year.

LEADVILLE.—John Cortellini, president of the Park Tunnel company of Aspen, has returned from an examination of the property and reports the orebody 10 ft. thick. A streak 4 to 10 in. wide sampled 90 to 150 oz. per ton. Shipments cannot commence until the new road is completed.

TELLURIDE.—Late shipments were as follows: Valley

View Leasing Co., 6 cars concentrate from the Matterhorn mill; Belmont-Wagner, 3 cars; Favorite, 1 car crude ore. A find of rich ore has been made by the Valley View Leasing Co. on the Matterhorn, where 12 in. of tetrahedrite with high silver content has been opened.

MICHIGAN

NO SHIPMENT OF COPPER EXPECTED DURING WINTER.—
RECLAMATION PLANT IN STEADY OPERATION.

HOUGHTON.—It is unlikely that any copper will be shipped East by rail this winter. Not only are freight-rates high, but there is limited demand for the metal and there are enormous quantities in storage in the Eastern centres. Lake shipments were heavy in November, amounting to 16,468,000 lb., which was much more than was produced that month. Most of this metal went into storage. Total shipments by water for the year were 69,624,000 lb., also far above the production basis for the six months of the season of navigation.

Although the curtailment program is in full operation at Calumet & Hecla, production from the conglomerate shafts should measure up to that of October. There has been little reduction of forces in this department and the operation of additional stope-scrapers in the various shafts will contribute considerably to the output. The scrapers that were in use in the Osceola branch have been transferred to the conglomerate. Under favorable conditions, one scraper has turned out 67 cars of 'rock' of a capacity of slightly over two tons each on a shift, while the ordinary record by hand-tramming has been from 12 to 14 cars. The use of the scrapers will materially decrease the cost. The 81st level haulage-way in the conglomerate department is progressing, although no great speed is being made. The rails have been laid practically up to the present terminal. Not only will the tunnel permit of deeper mining by means of sub-shafts, but it will enable the company to realize an immense production from its shaft pillars, once the haulage-way proceeds far enough to permit the closing of the shafts between No. 12 and the Red Jacket shaft, which is the ultimate aim. The time when the shafts will be abandoned, however, is still far in the future. It is estimated that it will be at least a quarter of a century before the solid strip of conglomerate 'rock' constituting the pillars is entirely removed, for there is a wall 8000 ft. long and 200 ft. wide paralleling each shaft at the Hecla and South Hecla branches. It was the original practice in mining to sink the shafts right into the lode, and to prevent the

shafts from caving there is a conglomerate wall 100 ft. on either side of each shaft. In the upper levels the walls contain as much as 75 or 80 lb. of copper per ton, and all the way down the pillars are just as rich as the arches and backs of stopes that now contribute considerable quantities of copper to Calumet's output. The removal of the pillars is done upward, a method that permits the 'rock' to drop by gravity through chutes. The closing eventually of all the conglomerate shafts except No. 12 and the Red Jacket will result in a considerable decrease in costs, inasmuch as all hoisting will be done through the Red Jacket branch. No. 12 will be used as a supply shaft. The haulage-way will be approximately a mile and a half long. The output of the Calumet & Hecla reclamation plant continues at better than 1,000,000 lb. monthly. It is estimated that the production of the plant for the year will be 15,000,000 lb., an increase of approximately 6,000,000 lb. over 1919 or 1918. Fixing the output for the year at 15,000,000 lb., the total recovery since the reclamation project started is close to 50,000,000 lb. and the huge sand pile in Torch Lake still contains millions of pounds of copper. There are prospects of even a higher recovery in 1921, for the reason that two additional flotation units will then be in operation. Work on the extension to the plant is progressing, the steel work having been completed. It is expected that the new units will start in the spring. They will permit the application of oil-treatment to all of the reclamation sand, 25% of which is now returned to the lake without being subjected to oil-treatment. Six furnaces are now 'down' at the Calumet & Hecla smelter. Two furnaces, each with a capacity of 1,000,000 lb. of refined copper per month, remain in operation.

Seneca's 5th level, north, has passed through a stretch of unusually rich ground in which barrel or mass copper predominates and the south level also is breasted in a good grade of 'rock'. The showing on this level is considered good, and mineralization apparently is heavier than on the levels above. The 3rd and 4th levels are still going forward in fairly good ground and will be continued. Sinking is under way, with the bottom slightly below the elevation of the 6th level. Both the north and south drifts on the 5th level are approximately 150 ft. long, and good progress is being made in extending them. In its development work, Seneca is making occasional shipments to the Baltic mill. During the early part of November, Gratiot, owned by Seneca, made a mill-test from its stock-pile at the mine. A total of 446 tons of 'rock' was stamped, yielding 33,704 lb. or 75.56 lb. per ton. This tonnage was taken from the stock-pile after the usual discard had been made from the run-of-mine. All of the 'rock' came from the development of the 13th level, south, of No. 2 shaft, which level, from the shaft southward to the Mohawk boundary, has shown good mineralization. Two raises are being made on the 13th to the 11th level and these have reached a height of 100 ft., showing good mineralization. The mill-tests indicate a copper content in both the Seneca and Gratiot higher than the most sanguine estimates.

NEVADA

FREIGHT-RATES ON ORE CONSIGNED TO WABUSKA SMELTER ARE REDUCED.

RENO.—The railroad-rate hearing before an examiner for the Interstate Commerce Commission has been concluded and each side has been given 30 days in which to file briefs. The mining interests of the State, through Henry M. Rives, secretary for the Nevada Mine Operators' Association, and others, made a strong protest against further increases, pointing out that the industry in Nevada in its present condition would be hit hard by another increase. K. K. Gartney, an examiner for the Interstate Commerce Commission, in the Wabuska smelter case, has ordered the Western Pacific railroad to establish a rate of \$3.53 per ton on ore shipped to Wabuska. This is taken to mean that the Wabuska smelter of the Mason Valley Mines Co. will be re-opened and enlarged, which would provide a market for copper producers over a large area in Nevada and California. The Wabuska smelter was closed because of a rate of \$9.10 per ton from Plumas county points and corresponding rates from Nevada districts as against \$8.80 to the smelter at Garfield, Utah, a condition that gave the Utah plants all of the ore that formerly went to Wabuska. The Mason Valley asked for a rate of \$3.50. The decision is considered of great importance to Nevada mining, and there is little probability that it will be reversed, according to S. W. Belford, attorney for the smelting company.

DIVIDE.—The south-east drift on the 800-ft. level of the Tonopah Divide is being driven in a shoot of ore that is believed to have been entered too far north-west to be the extension of any ore found on the fifth level and, particularly as the ore is sulphide, the find is considered to be of great importance. The ore has been of shipping grade for nearly 100 ft., according to reports, mine-car samples giving assay returns of as high as \$400 per ton. The average value is about \$35, according to rough sampling. The drift on the 1000-ft. level, also being driven south-east, the direction of the rake of the ore-shoots, is in low-grade material and it is close to where the extension of the ore on the 800-ft. level should be entered.

TONOPAH.—A station is being cut at the 1880-ft., or bottom, level of the Victor shaft of the Tonopah Extension. From this point the western part of the company's territory will be explored. The McKane shaft, from which connection will be made with the 1540-ft. level of the Victor, is now 1350 ft. deep and sinking is being continued.

No work has been done to determine the width of the ore on the 800-ft. level and it is only known that it is wider than the drift. The shoot entered 300 ft. south-east of the shaft on the first, or 165-ft., level proved to be 125 ft. long and a drift is being continued beyond it in a search for another shoot. The drift on the second level will be extended to prospect that on the first. Shipments to the Belmont mill at Tonopah continue at a rate of 50 tons of \$30 ore daily. A pipe-line is to be laid from

the Gold Reef shaft to the Tonopah Divide, which will eliminate the heavy expense of hauling water from Tonopah. The Gold Zone has shipped 15 to 20 tons of \$15 to \$20 ore from the 700-ft. level and the 150-ft. winze from the 500. The net return to the company was more than \$10 per ton. This ore, thought to be in a vein distinct from the main ore-channel in the Tonopah Divide, is now believed to be the main Tonopah Divide vein, faulted. The Brougher has opened what is considered to be the most important ore-shoot found thus far. This find was made in a drift driven south-east, or toward the Tonopah Divide, from the 100-ft. point in a winze from the 500-ft. level. The ore has now been opened for nearly 50 ft. and the average value is reported to be \$20 to \$25. The winze

CARLIN.—The Lynn Big Six, operating a low-grade gold mine at Goldville, 20 miles north of here, is building a 100-ton amalgamating-concentrating mill. The company has opened, through an 800-ft. cross-cut tunnel at a depth of 100 ft., five veins 5 to 35 ft. wide, two of which have been prospected with drifts. There also is a 370-ft. inclined shaft with several hundred feet of drifts from it. Two 100-ton test-runs gave an extraction of 70% of the gold. At one point a winze has been sunk 110 ft. in low-grade ore. The formation consists of bedded rhyolite, intersected by dikes of rhyolite and porphyry. The gold is in a vein-filling of broken quartz and rhyolite striking parallel to the dikes. The Lynn Big Six is controlled by Utah men.

SIMON SILVER-LEAD MINE, NEAR MINA, NEVADA

is being continued to 1000 ft., where connection will be made with the Tonopah Divide.

ELY.—It is reported that a drill-hole being sunk 900 ft. east of the Star Pointer shaft of the Ruth mine of the Nevada Consolidated has been in 1 to 3% copper ore for 260 ft. below a depth of 710 ft. This is said to be a new find 200 ft. below the level of the bottom of the main working shaft.

GOLDFIELD.—The Florence has resumed work, the order coming at a time when it was expected the company would be idle much longer. It is understood the Eastern interests have furnished funds to complete the south-east cross-cut on the seventh level and prospect the vein. It is said there is now ample money available to do enough work to determine definitely whether there is ore in this vein. S. J. Connelly, representing the Portland company of Cripple Creek, is inspecting the air-compressors of the Consolidated with a view to purchasing one or more for his company, which is said to be preparing to sink to 3500 ft. from the present depth of 2500. The Consolidated has two of the largest electrically operated compressors in the country.

STONEWALL.—A 32,000-gal. tank has been bought by the Yellow Tiger for the storage of oil in an effort to reduce costs. A new Waugh turbo drill using 1½-in. round steel will be used when work is resumed in the tunnel and a steel-sharpening plant has been completed. The present work is confined to surface prospecting, but plans for raising additional money through the sale of treasury stock are "progressing nicely", according to Gordon M. Bettles, manager, and it is expected that work in the tunnel will be resumed in a short time. Mr. Bettles estimates that the tunnel will be in extremely hard porphyry for 200 or 300 ft. more.

CARSON.—Only eight men were killed underground and two on the surface in the Nevada mining industry during 1920, as against 16 last year and 26 in 1918, according to a report to be issued by Andrew J. Stinson, State Mine Inspector. The report will recommend more rigid examinations for hoist engineers and the issuance of licenses in three grades, according to the applicant's knowledge of hoisting-machinery. Physical examinations also will be recommended as compulsory for hoist engineers in the State.

UTAH

WAGES ARE REDUCED BY UTAH MINING COMPANIES.

SALT LAKE CITY.—On December 14, the metal-mine operators of Utah announced that on January 1, wages of employees in all of the underground mines in the State would be reduced 75c. per shift. At present miners are receiving \$5.25 and muckers \$4.75 per shift, so the new rates will be \$4.50 and \$4.00, respectively. On December 17, R. C. Gemmell, general manager for the Utah Copper Co., announced that all skilled labor employed by the company would be reduced \$1 per shift and unskilled labor 85c. About 2000 employees will be affected by this reduction at the Utah Copper properties alone. At the same time, Gemmell announced that operations would be suspended at the leaching-plant at Garfield, and that all construction work would be discontinued. This will result in several hundred men being laid off. During November the Utah Copper sold only 2,800,000 lb. of copper, as against a production of 9,120,000 lb.; during the first 11 days of December copper sales were but 900,000 lb. The average price obtained for the November sales was 14.85c. per pound, and for the December sales, 14c. per pound, whereas during the third quarter of the year it cost the company 17.156c. per pound to produce its copper; for several months past, the Utah Copper has been operating at a loss. Recent developments have rendered it necessary to make a still further curtailment in production, and the management feels that, so far as the employees are concerned, it is better to make a reduction in wages than to suspend operations entirely. There is now a surplus of labor in every mining camp in the State.

EUREKA.—The Tintic Standard Mining Co. on December 11 declared a dividend of 20c. per share, which was paid on December 23. This disbursement totaled \$234,940, and brings the grand total up to \$1,429,962. E. J. Raddatz, president of the company, has announced that a new shaft, to be known as No. 3, will be sunk at a point about 1600 ft. to the north-east of the No. 2 shaft and within 100 ft. of the company's new railroad. It will be the largest shaft of the three, containing four compartments, being 6 by 18 ft. Machinery has already been purchased and the work will be rushed. Most of the company's output of ore is coming through the No. 2 shaft, and when the milling plant is in operation early in the new year, this shaft will be taxed to its capacity. About 450 mine-cars are now being hoisted daily through this shaft; the equipment is capable of handling 600 cars.

The United States Smelting Co., of Midvale, has taken a lease on part of the Dragon Consolidated mine. About 50 tons of iron ore is now being extracted by the smelting company daily, and this amount will shortly be increased to 100 tons. The Dragon company will receive a royalty of from 50 to 75c. per ton.

The Eagle & Blue Bell Mining Co. has posted a dividend of 10c. per share, to be paid out of earnings, and a dividend of 15c. per share, to be paid out of reserve for depletion, as return of capital, both payable on December 23. As there are 893,146 shares outstanding, this will

call for the payment of \$222,286, and bring this year's disbursements up to \$311,605, a dividend of 10c. per share having been paid in April. The grand total to date of such disbursements is \$1,562,009. The company is controlled by the Bingham Mines Co., and is one of the principal lead-silver producers in this district. A recent statement by Imer Pett, general manager, was to the effect that the property was never in better physical condition, and shipments could be greatly increased if it were not for the unsatisfactory condition of the lead market.

From present indications, the Chief Consolidated mine will break all records for metal output during the present year. During the first nine months the output of silver was 1,950,585 oz.; of gold, about 4000 oz.; and of lead, 9,499,119 lb. It is expected that the current quarter will result in the production of about 3,000,000 lb. of lead, whereas the total lead output for 1919 was 5,979,588 pounds.

PARK CITY.—At a meeting of the directors of the Daly West Mining Co. on December 13 the regular quarterly dividend of 25c. per share was declared, payable December 24. This called for the payment of \$62,500, and brings the grand total of such disbursements up to \$6,831,000. At the same meeting, the directors of the Judge Mining & Smelting Co. voted to pass the dividend for the current quarter. S. G. Taylor, treasurer, issued a letter to the stockholders, stating that this action had been taken owing to the low market prices of metals, increased freight and smelter-rates, and excessive extraction costs. It was further stated that labor conditions show a decided improvement of late, but owing principally to metal-market conditions, the directors deemed it advisable to retain a substantial balance in the treasury.

The milling plant at the Glenallen property was completed on December 10 and operations were started on December 13. Within 30 days the flotation department, consisting of five Jones-Belmont machines, will be in operation. The mill has a capacity of 100 tons per day, although it is expected this tonnage can be built up to 225 tons per day. Tests indicate that a 90% extraction can be made on ore averaging 60c. in gold, 9 oz. silver, 9% lead, 16% zinc, 2% copper, and 14% iron. A lead-silver concentrate will be produced, while the zinc recovered will be stored until more favorable market conditions prevail. Originally the greater part of the Glenallen property was known as the Glencoe group. In 1893 the property was closed, and operated spasmodically without results until three years ago when the present company was organized. Some months ago J. S. Weeks of New York examined the mine, and it was on his recommendation that the milling plant was constructed. James B. Allen is general manager for the company.

Additional ore has been developed during the past few weeks at the Silver King Coalition, according to M. J. Dailey, mine manager. On the 1300-ft. level, a drift to the north-west from a cross-cut to the O'Brien zone, has opened a good face of ore in the same bedding in which the ore on the 1100-ft. level is found.

BRITISH COLUMBIA

DECISION IN LITIGATION OVER THE ENGINEER MINE.—CANADA COPPER CORPORATION SUSPENDS OPERATIONS AT ALLENBY.

VANCOUVER.—Justice Morrison rendered judgment on December 8, dismissing the claim of W. Pollard Grant, a lawyer of this city, for a one-fourth interest in the Engineer mine, at Atlin. The Engineer probably contains richer gold ore than any other mine in the Province. In the fall of 1918 the Mining Corporation of Canada sent two engineers to make an examination of the mine, but in returning from the property with James Alexander and his wife, the owners, they shared the fate of all the other passengers on the ill-fated 'Princess Sophia', which

PRINCETON.—After running it for 52 days, the Canada Copper Corporation closed its plant at Allenby on December 11; the mine was closed two days earlier. The corporation has made the following announcement: "Owing to the low price of copper, which has been gradually dropping, it has become necessary to close down the mine and plant at Copper Mountain and Allenby." Some time before closing, the company asked the men to accept a reduction of 50c. per shift in the wage-scale. After holding a number of meetings the majority refused this offer, and the directors ordered the closing of the plant. Some 400 men have been thrown out of work, about 60 of whom are married and have families. The single men have left for other places, but with the Britannia closed and Granby and Trail reducing their staffs,

TOOELE PLANT OF THE INTERNATIONAL SMELTER COMPANY

sank in the Lynn Canal in October of that year. Prior to this time Capt. Alexander had worked the mine in a desultory way for ten years, and from time to time had taken out some fabulously rich ore. The first-grade ore was crushed in a small jaw-crusher and pulverized in quantities of 600 to 1000 lb. in a five-foot ball-mill. Two or three flasks of mercury were then added, and the mill revolved slowly for 20 minutes. The amalgam was separated from the pulp by washing, and was treated in the usual way. On one occasion 160 lb. of ore yielded 296 oz. of gold. A great deal of open-cutting and surface stripping has been done, exposing altogether 25 veins, ranging in width from a few inches up to 275 ft. Tunnels have been driven on the more promising of these, but unless really rich ore was found the work was dropped. One bonanza shoot, 30 ft. long and varying from the thickness of a knife-blade to 18 in., has been stoped from the surface to 275 ft. In some of the pinched places the ore in this shoot contained more gold than quartz. At least two of the big Ontario silver mining concerns have their eyes on this mine, and it is likely that negotiations will be concluded this winter. Ben Nichol, who owns the claims adjoining the Engineer, has gone to Atlin to prepare for the development of his claims next spring.

it is difficult to see where they will find work in this Province. Already about 1200 men have been laid off within the last two months by the copper companies of the Province.

TRAIL.—Despite the downward trend of metal prices, the Consolidated M. & S. Co. is holding up the output of its mines. The closing of the Canada Copper, it is feared, may mean the closing of the copper-smelting and refining department at the smelter. The company has made large expenditures to take care of Canada Copper's concentrate. These include the erection of three sintering furnaces, and the practical doubling of the capacity of the whole copper-treating plant. The power-line, too, to Copper Mountain was erected by a subsidiary company. Rossland Velvet Mines, Ltd., has been incorporated at Rossland with a capital of \$300,000 to take over and operate the Velvet mine. The Velvet was re-opened this year and has shipped 310 tons to the smelter. The Exchequer and Athabasca groups, on Toad mountain, two and a half miles from Nelson, have been purchased by the owners of the California group, in the same district. There is a 10-stamp mill, cyanide plant, compressor, and power-plant on the Athabasca.

ALICE ARM.—A good body of ore assaying 300 oz.

silver per ton has been found at the North Star mine. Ten horses have been taken to the mine, and will be employed during the winter in hauling ore to the Dolly Varden railway, where it will be stored until the spring. It is expected that 15,000 to 20,000 tons of ore will be taken out during the winter. A full force of men will be employed throughout the winter. E. W. McQuade, superintendent of the Moose mine, reports that development work is progressing well. During the last month the lower tunnel has been advanced 45 ft. and the upper one 36 ft.; the latter is being driven on a six-foot lode of good ore. The new owner of the Alice Arm hotel has made arrangements to commence enlargements and improvements to the hostelry at the beginning of the year. This will be a great boon to the many mining men who visit the district.

ONTARIO

WRIGHT-HARGREAVES MILL-CONSTRUCTION IS PROGRESSING.

COBALT.—Labor is abundant but wages remain unchanged. The McKinley-Darragh and the Mining Corporation have reduced their staffs, but are still producing at about two-thirds capacity. During November the Nipissing mine produced \$190,219, as compared with \$184,578 in October. The November output is valued on a basis of silver at 69c. per ounce, as compared with 82c. in the preceding month. In his report to the president and directors, Hugh Park, manager, states: "No new veins were opened during the month. Production was obtained from the older stopes, assisted to some extent by development work being done on several small veins on both sides of the lake. The low-grade mill treated 6000 tons. The high-grade plant treated 192 tons. The refinery shipped 250,067 fine ounces of silver." On January 20 the Nipissing will disburse a dividend of 5%, as well as a bonus of 5%, making a total distribution of \$600,000. A statement just issued by the Ontario Bureau of Mines, covering the first nine months of 1920, shows a silver output of 7,831,143 oz., valued at \$8,435,088, in 1920, as compared with 7,475,396 oz., valued at \$7,898,220, in the corresponding period of 1919, the increase amounting to \$536,868. The Nipissing continues to be the heaviest producer, with the Mining Corporation holding second place.

PORCUPINE.—A dividend of 1%, declared by the Hollinger Consolidated, payable December 31, is the ninth to be paid this year, making total disbursements of \$2,214,000. Coal is being rushed to the mine so as to keep the auxiliary steam-plant in full operation. Production for the current year with the mill working at an average of about two-thirds capacity, will approximate six million dollars.

At the McIntyre the ore-reserves are being rapidly increased by the development of the new vein-system, lying about 400 ft. south of No. 5 shaft, where results have exceeded expectations. On the 1375-ft. level the new vein shows a width of about 20 ft. with high gold content. The mill is running at capacity with an improvement in the grade of ore being treated.

KIRKLAND LAKE.—Preparations are being made at the Wright-Hargreaves for the opening of the new mill early in the new year. The mine is in good condition to keep the mill steadily supplied with ore. Most of the ore developed is on the 400-ft. level and is high in grade. The workings of the central shaft are being connected with those of the North shaft, through which the ore will be handled. Stations are being opened up at the 100, 200, and 300-ft. levels preparatory to undertaking lateral work. The main ore-shoot, which has been followed up for 400 ft., has a width of 20 feet.

LARDER LAKE.—Diamond-drilling has been carried on by the Associated Goldfields. About 40 holes have been sunk, many of them between 700 and 1000 ft. in depth. The majority have been directed to explore the broad gold-bearing belt extending through the Kerr-Addison and Reddick properties. Ten thousand feet more of diamond-drilling remains to be done on the present contract. The work has been stopped, to be resumed in the spring.

MEXICO

EXPORT DUTIES ON COPPER WAIVED.

AGUA PRIETA.—Material for the construction of a railroad from Naco, Sonora, by way of Agua Prieta, to Guzman, Chihuahua, connecting there with the Mexico Northwestern, is arriving at Agua Prieta. The material assembled here is shipped from Eagle Pass, Texas, is all new, and is sufficient to equip 1000 men. J. J. Slade, an American engineer, is in charge of construction.

Until the price of copper goes to more than 15c. on the New York stock market, export duties on shipments of ore and copper from Mexico into the United States have been removed by the Mexican government. The order is retroactive to December 1, and indicates that duties paid subsequent to that date will be returned to the companies. This action is taken as an effort to cope with the general depression in the copper market, in the hope that copper companies operating in Mexico will not be forced to suspend operations.

NACAZARI.—The Moctezuma Copper Co., a branch of the Phelps Dodge Corporation, will not close-down but will continue operations on a restricted scale, according to P. G. Beckett, general manager for the Phelps Dodge Corporation. Mr. Beckett said that the waiving by the Mexican government of the export duty on copper would help, but that it will not result in an immediate increase in the scale of operations.

CANANEA.—The Cananea Consolidated Copper Co. will suspend operations on January 15, 1921, as was announced a few weeks ago, in spite of the removal of the export duty on copper and copper ores, according to reports. Adolfo de la Huerta, minister of the treasury, and General P. Elias Calles will arrive at Nogales before January 15 to use their offices in an effort to adjust the difficulties of the company and to avert the shut-down. It is estimated that suspension of operations by the company would affect about 20,000 persons, directly or indirectly.

THE MINING SUMMARY

ARIZONA

Kingman.—The Tennessee and Schuylkill mines of Chloride have gone into receivership, George N. MacBean, of Holbrook, Arizona, having been appointed receiver. Frank A. Garbutt, of Los Angeles, California, it is reported, holds a mortgage of \$300,000 on the property.—The drift from the 420-ft. level of the Diamond Joe mine is said to have cut ore 30 in. wide, which will run as high as 100 oz. in silver per ton besides some lead.—Connection has been made in the drifts being run by the Tom Reed and the United American at Oatman. This connection is on the 400-ft. level of the Tom Reed. The Tom Reed drift was run in ore for 300 ft. prior to holing through. This ore carries visible free gold and is reported to be of high grade. In all, the ore-shoot is said to be over 500 ft. long, 200 ft. being in United American ground.

CALIFORNIA

Amador County.—Unwatering of the Argonaut and Kennedy mines is proceeding rapidly. The pumps on the lower levels that were flooded by the advancing waters have been recovered and found in excellent condition, and are aiding the main pumping plant in clearing the deeper workings. The shafts and drifts thus far unwatered have been found in excellent shape, and will require little in the way of repairs. The work is being carried on at both properties at the expense of the Argonaut company, which is anxious to reach an approximate depth of 4800 ft. where a large body of rich ore is exposed.

Conditions at Sutter Creek show steady improvement despite the many handicaps affecting gold mining. The Central Eureka continues to develop excellent ore on the 3900-ft. level, and is maintaining heavy shipments of profitable ore to the mill. In the Old Eureka recent work has exposed promising ore in new territory.

Operations have been resumed at the Fremont Consolidated, near Amador City, after an idleness of two years. The Gover shaft has been completely unwatered and large areas of the Fremont shaft also cleared, with good ore reported in sight at several points. The property is now controlled by a new coterie of owners, with Edwin Higgins manager. A few years ago the property ranked high among the leading dividend-disbursers of the Mother Lode region.

Nevada County.—According to reports new rich ore-shoots have been uncovered in the bottom levels of the Empire and Pennsylvania mines of the Empire Mines Co. The company is operating its 80-stamp mill at full capacity and its monthly output is estimated at close to \$100,000. Within the past six weeks the company has materially increased its working force and started development of new territory.

IDAHO

Bonnors Ferry.—Twenty-four men are working for the Cyanide Gold Mining Co., 25 miles north-east of here. Each man is paid \$1 per day and takes the rest of his wages in stock in the company. "All the men are doing this and are glad to do so, in fact, some of them put the dollar they receive back in additional stock," said J. B. Ellis, president of the company. "We are installing a mill, tram, and power-plant, and as soon as the tram is completed we will commence operation of the mill."

Coeur d'Alene.—C. A. Gray, secretary of the International Mining & Metal Co., says that the drift now being driven to the west of the vein is 30 ft. from the end of the 300-ft. tunnel. The property is developed to a depth of 260 ft. by a 300-ft. tunnel and an 11-ft. winze. Ore from this winze and tunnel assayed 2% copper, 27% zinc, 24% lead, and 9 oz. silver.—The U. S. Silver-Lead Mining Co. reports that a seven-foot vein has been cut with 1½ ft. of high-grade shipping ore. Drifting is being done to determine the extent. In the tunnel, 125 ft. above, the ore-shoot was 350 ft. long.—Better zinc-lead ore is found on the No. 10 level of the Callahan Zinc-Lead mine than was found on the No. 9 level, 200 ft. above. This seems to disprove the fear that the zinc ores of the district would not persist with depth. Although the mill of the company is closed and no ore is being mined, development work continues. The vein on the No. 10 level is four feet wide. When the extent of the orebody is determined the shaft will be sunk 200 ft. farther.—According to reports, the United States Supreme Court has denied the application for a writ of certiorari asked by the Federal Mining & Smelting Co. against the Star Mining Co., involving title to the Star-Morning vein at Mullan. This means that the Star mine obtains title to the valuable vein west of the Morning end-lines. In addition, there is an accounting to be made of ore extracted by the Federal company from that part of the vein. This is expected to bring the Star owners between \$500,000 and \$1,000,000. The Star mine is now under option to the Bunker Hill & Sullivan Mining & Smelting Co. for approximately three-quarters of a million dollars, subject to the decision of the Supreme Court. Awaiting the decision, no work has been done recently.

NEVADA

Good Springs.—The Yellow Pine Mining Co. closed its mines and mills, owing to the low prices of lead and zinc. Some weeks ago, the company considered such action, and the miners and millmen accepted a cut in wages in order to keep things going, but as metal prices continued to decline, there was no alternative but to suspend operations.

OREGON

Gold Hill.—Charles A. Knight, who three years ago acquired the Millionaire gold mine, an old-time producer, situated three miles east of Gold Hill in the Blackwell Hill district, is preparing to resume operations. He has spent a large sum of money in re-opening the old works, re-building the shaft-houses, remodeling the mill, and re-building the electric power-line to the mine, which was dismantled early in the war period. The mill has two 1500-lb. Nissen stamps with circular discharge and two 10-ft. amalgamating plates; it has a rock-crusher and a Standard concentrating table.—Among the large hydraulic placer properties which control large flows of water and are not affected by dry seasons is the Sterling mine, in the Jacksonville district, controlled by R. S. Bullis, of Medford. A large electric-power pump has recently been added to the equipment, by means of which pressure at the nozzle has been increased to the equivalent of a head of 200 ft. The gravel is so thoroughly cemented that much of it must be broken with powder before using the giants. The deposit is 20 to 40 ft. thick and about 400 ft. wide. The slope of the bed is about 2 ft. in 100. The

value of the gravel is about 40c. per cu. yd., and the total production of the mine is said to exceed \$3,000,000. The length of the working season varies from 7 to 10 months.

Waldo.—The Esterly mine, generally known as the Logan placer, is owned and operated by George M. Esterly and associates of Seattle. Forty miles of ditches carry water from the higher portions of the east and west branches of the Illinois river to supply the mine. The head is 325 ft. The gold is generally fine, running about 15c. per cubic yard; it is accompanied by some platinum, as well as a little osmium and iridium. The output of this mine is about \$60,000 annually. The area mined varies greatly in width, averaging an eight of a mile. Formerly a hydraulic elevator was used to remove the tailing from the pit, with a lift of a maximum of 15 ft., but recently a tail-race tunneled through solid rock at a cost of \$60,000 has been completed which will double the output of the mine. The other important hydraulic placer mines in the Waldo district are the Deep Gravel or Wimer mine, and the High Gravel or Osgood mine.

WASHINGTON

Pullman.—A 12-weeks special course in mining, geology, assaying, ore-testing, metallurgy, mineralogy, and mine-surveying, offered by the School of Mines and Geology of the Washington State College, is to begin January 3, 1921. The course is designed for men interested in mining but who have not had the advantage of special college training and is open to all over 21 who can read and write and who are able to do ordinary arithmetical problems. In the assaying course a deposit of \$25 is required of each student, partly to defray the cost of fuel, fluxes, and chemicals. Otherwise the expense to the student is the cost of a few books and his living. The instruction is of a laboratory character, the student being taught by doing or observing the things he is learning. The use of the lecture-room is largely confined to the description and illustration of the best methods and practices in mining and metallurgy. In addition to an excellent corps of instructors the school equipment gives the student the best facilities for work. In the mining building is machinery for sampling, amalgamating, concentration, cyaniding, smelting, and a complete flotation-testing laboratory.

WYOMING

Cokeville.—Several years ago W. A. McKinney of Salt Lake City and associates acquired some mining property 30 miles north-east of here, consisting of 25 claims, now in the process of patenting, and a mill-site on Smith's fork of Bear river. This property was discovered nearly 30 years ago, but on account of its inaccessibility, practically no work has been done. Recently high-grade ore has been found in No. 4 tunnel level, which has been driven 600 ft. for the purpose of cutting the main lode at a vertical depth of 400 ft. below the tunnel above.

MANITOBA

Flin Flon.—The Federal government has agreed to waive all royalties on copper for five years. It is believed that this will have an important effect on the operations of the Flin Flon syndicate. The initial payment of \$1,000,000 will fall due on March 1, 1921, and provided those now exploring the property receive an assurance that a railway will follow the present surveys within a reasonable time, in all likelihood the purchase will be made. The mineral resources of the three prairie provinces, Manitoba, Saskatchewan, and Alberta, belong, as yet, to the Federal government, and this has complicated matters. There may be a change before many months, and then the negotiations with the Flin Flon interests will come under the sole purview of the Manitoba government, which is understood to be most anxious to assist in the building of a smelting centre north of the Saskatchewan.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

S. M. Parker, of Nicaragua, is in San Francisco.

D. M. Riordan has returned from New York to San Francisco.

Frank M. Smith has returned from Los Angeles to Spokane.

Ellsworth Daggett, of Salt Lake City, is sojourning in San Francisco during the winter.

C. C. Broadwater, of the Merrill Company, San Francisco, has returned from London and Paris.

L. S. Cates, general manager for the Ray Consolidated Copper Co., was in San Francisco last week.

C. W. Purington expected to leave Shanghai on December 10, on his return from Eastern Siberia to London.

G. E. Drewitt has accepted the position of manager for the Federal Coals, Ltd., at Lethbridge, in Alberta, Canada.

L. D. Ricketts is a visitor in the Warren district attending to matters connected with the Calumet & Arizona Mining Co.

Walter R. Vidler has returned to Los Angeles, having completed a month's examination work near Culiacan, Mexico.

Morton Webber is at the Empire mine, at Mackay, Idaho. He spent several days in Salt Lake City on his way from New York.

C. B. Lakenan, general manager for the Nevada Consolidated Copper Co. at McGill, Nevada, spent a few days at Salt Lake City recently.

D. C. Jackling left New York on December 17 for the West. He spent two days at Salt Lake City and arrived in San Francisco on the 23rd.

Alexander Mackay, president, and **F. S. Stephen**, director, of the Dundee-Arizona, are visiting the company's property at Jerome, from their home in Scotland.

Frank P. Knight, president of the Iron Cap Copper Co., and **J. Judson Dean**, vice-president, are visiting the properties of the company in the Globe district.

B. Shutts and **H. E. Hecker**, officials of the American Ores & Asbestos Co., have recently inspected the properties of the Shaff-Regelman properties at Crysofile, Arizona.

F. A. Malins has been appointed consulting metallurgist to the Dos Estrellas Mining Co., El Oro, Mexico. **W. B. Rhodes** succeeds him as superintendent of the El Cedro mill.

Russell G. Lucas, of the legal firm of Dickson, Ellis, Lucas & Adamson, Salt Lake City, has accepted a position with the Utah Copper Co. in charge of the industrial relations department.

Arthur H. P. Moline, general manager for the Bendigo Amalgamated Goldfields, at Bendigo, Victoria, is visiting representative mines in California, Utah, and Colorado. He is at Salt Lake City now.

Arthur C. James and **William C. Osborn**, directors of the Phelps Dodge Corporation, in company with **Walter Douglas** and **P. G. Beckett**, have been visiting the properties of the Phelps Dodge in the South-West.

R. S. Lewis, head of the Department of Mining and Metallurgy in the University of Utah, has been granted a year's leave of absence. He will spend that period in field study of mining and in preparing a course of lectures on coal mining.

A. G. Mackenzie, secretary of the Utah chapter of the American Mining Congress, is at Chicago attending the hearing before the Western Trunk committee, regarding a reduction in freight-rate on bullion from Western smelters to the Atlantic seaboard. **George E. Collins**, governor of the Colorado chapter of the Congress, is also in attendance.

THE METAL MARKET

METAL PRICES

San Francisco, December 21

Aluminum-dust, cents per pound	65
Antimony, cents per pound	9.50
Copper, electrolytic, cents per pound	14.00—14.50
Lead, pig, cents per pound	5—6
Platinum, pure, per ounce	\$85
Platinum, 10% iridium, per ounce	\$125
Quicksilver, per flask of 75 lb.	\$50
Spelter, cents per pound	9.50
Zinc-dust, cents per pound	12.50—15.00

EASTERN METAL MARKET

(By wire from New York)

December 20.—Copper is inactive but easy. Lead is dull and lower. Zinc is quiet and declining.

SILVER

Below are given official or ticker quotations for silver in the open market as distinguished from the fixed price obtainable for metal produced, smelted, and refined exclusively within the United States. Under the terms of the Pittman Act such silver will be purchased by the United States Mint at \$1 per ounce, subject to certain small charges which vary slightly but amount to approximately three-eighths of one cent. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

CHARLES M. SCHWAB ON ECONOMIC CONDITIONS

Speaking as president of the Pennsylvania Society of New York, at the annual dinner of the society, at the Waldorf-Astoria, Charles M. Schwab said, in part:

"The existing moment is full of difficulties and complexities. Here and there you find prophets of despair. But I want to go on record here as saying that nothing could be healthier for American business than the very condition through which we are now passing. It had to come. I only wish it had come sooner. The severer the storm is now, the quicker it will be over and the sooner we can emerge into clear weather and shape our course upon the sea of prosperity. Business in the United States ever since the War started had been, until very recently, upon a false basis. The disposition of many manufacturers had been to say not: 'Let me see your costs sheet,' but 'Let me see your statement of profits'."

"The result of this experience through which we have passed is that our costs have been inflated and we have had in America both our business institutions and American individuals generally indulging in wasteful and extravagant methods. The supreme virtue of the existing situation is that it is compelling every business man in America, in fact, every individual in America to examine thoroughly his costs of doing business and his costs of living. The result of it all is to force business and to force individuals to start to economize and to save."

"The great need of the world today is to work hard and save. This applies not alone to the laboring man, but to the man of great means. There is no place in America today for the loafer. I hear men say that the greatest need of the hour is the liquidation of labor. In saying this many have in mind the high wages now being paid to labor and industry, and mean that labor must adjust itself to a new standard of living. Now the laboring man is primarily interested not in the amount of money paid to him, but what his money will buy. If the cost of living comes down there is no question that our American laboring man can maintain his present standard of living even though his wages as stated in dollars amount to less than the sum than before."

"In the steel industry one-half the total cost of making steel is the cost of labor. You can, therefore, see how important efficiency and labor cost are in all items of manufacture. The laboring man is entitled to his full share for the contribution he makes to the value of an article. The laboring man should be taken into the fullest confidence of his employers. He should be so sure of getting his fair share of the wealth he produces that he will work with zeal and enthusiasm."

"Certain it is that unless the great body of men throughout the world work with might and main to restore that which has been lost by the destructiveness of war, this world will sink to a lower level of civilization than we have been accustomed to enjoy. Certain it is, too, that labor must work as it has never worked before if it is to produce a sufficient quantity of goods to make possible the standard of wages which have been enjoyed during these years of inflation and of supreme prosperity. Not merely increased production, but increased efficiency in production is essential. We are getting relieved of the impurities in our business life. The process is not complete yet. It may take some little time longer. But the patient will in time be cured and when he is cured the great body of American business will emerge with a vigor and an energy the world has never known before."

Eastern Metal Market

New York, December 15.

There is no animation to any of the markets, the price tendency in most cases being steady.

The copper market is very quiet and prices are steady.

Buying of tin is very light. Prices generally follow the ups and downs of the London market.

The lead market is steady with a fair amount of buying.

The zinc market has lost some of its recent strength and is lower.

Antimony has declined with the silver market.

IRON AND STEEL

The slowing down of business is more pronounced at many steel plants and the problems of cost reduction are uppermost, says 'The Iron Age'. Work is being rearranged to save the overtime resulting from the basic 8-hour day. Reductions in wages amounting to 15% and in some cases more will be made on January 1 by some important independent companies. Eight-hour turns are being introduced in some cases in order to give more men work, but because of scant orders there are only two shifts instead of three.

There are some reports of wage-reductions already made at some plants and one case of an offer by employees to co-operate in plans for reducing labor-cost.

There is sharper contrast between the Steel Corporation's rate of operations and the average rate at independent mills. The Steel Corporation increased this week to 90% of steel-works capacity and added a blast-furnace at Edgar Thomson and another at Gary. At the same time a further curtailment of output has been made at various Ohio and Pennsylvania independent works and more merchant blast-furnaces are stopping, especially in Virginia and eastern Pennsylvania.

Taking the country's steel capacity in its entirety, probably 65 to 70% is active this week. This is expected to be reduced next week and through the holidays more mills will be idle than at any time since the holidays of 1914-'15.

The world-wide recession is accentuated by further shipyard cancellations in Great Britain, including four 10,000-ton boats for Belgium. Due partly to the coal strike, November pig-iron production in Great Britain was 403,000 tons, compared with 692,200 tons average for the other 10 months of 1920, and the steel output for the month at 403,800 tons compares with a 10-months average of 780,500 tons.

COPPER

The market is quite steady but without feature or animation. Buying by domestic consumers is at a standstill and quotations are largely nominal at 14c., New York, for early delivery and 14.25c. for first quarter. There is a fair business being done in foreign sales, all for early delivery, indicating low stocks in Europe and other countries. No improvement in the domestic situation is expected this year, but some revival of buying is looked for in January.

TIN

Press and private advices yesterday were that the Malay government had advanced its minimum price from an equivalent of £226 per ton, c.i.f. New York, to £243 and this has, for the time being, upset the market. Spot Straits yesterday was variously quoted at 32.50 to 33.50c., New York, against 33.50c. on Monday. There was considerable activity on the New York Metal Exchange yesterday when 100 tons was sold. Of this 75 tons for future shipment went at 34.25 to 35c., while one lot of 25 tons was sold under the rule at 30c., a ridiculously low price. On the 8th a 25-ton lot was sold under the rule at 35.62½c. There was a fairly active

business on December 8 when dealers bought quite freely of future shipments, December-January, at 37c. Aside from these developments the market has been quiet. The decline in silver has led to the appearance of some Chinese tin which sold on December 8 at 34.50c. for December shipment. Arrivals thus far this month have been 1575 tons with 2450 tons afloat. The London market is lower with spot standard at £212 10s., future standard at £216, and spot Straits at £213 10s., all about £11 lower than a week ago yesterday.

LEAD

Since the market settled to the 5c. level, both New York and St. Louis, there has been some good buying but it has not been animated. There has lately developed a weakness in London which has again foreshadowed the possibility of further imports which has put a damper on the market. It is now exceedingly quiet and a little lower at St. Louis. We quote the market for early delivery at 5c., New York, or 4.75c., St. Louis. The London market yesterday declined £23 per ton for prompt delivery and any further recession is likely to cause weakness here and lower prices, because of importing competition possible at 5c.

ZINC

After a brief period of animation and higher prices the market for prime Western has again declined, due largely to a weaker London market and the consequent possibility of imports. Prime Western for early delivery is now quoted at 5.90c., St. Louis, or 6 to 6.10c., New York, the latter being influenced by imported metal still available. There is almost no demand. Stocks in the hands of producers have slightly increased according to the November statistics, but the recent buying has brought out the fact that consumers' stocks are very low. The technical position of the market is considered favorable.

ANTIMONY

Largely in sympathy with the lower values for silver, antimony is easy with wholesale lots for early delivery quoted at 5.50c., New York, duty paid.

ALUMINUM

The leading interest's quotation for virgin metal, 98 to 99% pure, has not been lowered as reported, but continues at 32.90c. f.o.b. producer's plant. Other sellers are quoting the same grade at 23 to 25c., New York.

ORES

Tungsten: The market is stagnant and prices are nominal at \$4 per unit for Chinese ore and \$5 for Bolivian.

Ferro-tungsten is quoted at 59c. per pound of contained tungsten in a quiet market.

Molybdenum: There are no developments nor demand and quotations are nominal at about 65c. per pound of MoS₂ in regular concentrates.

Manganese: High-grade ore is unchanged at a nominal quotation of 42 to 50c. per unit, seaboard, in the absence of any demand. Imports are heavy and stocks are larger.

Manganese-Iron Alloys: There is a complete absence of any demand for ferro-manganese and it is difficult to state at what price it can be bought. As low as \$140, seaboard basis, can certainly be done and perhaps lower. Spiegeleisen, 19 to 22%, is down to \$60, furnace, at which 100 tons has been sold. Inquiries are limited to one or two carload lots.

Continued offerings by the Bank of France, combined with extremely poor trade conditions in China and India, as well as speculative activity, have been responsible for a further decline in silver.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

NORTH STAR MINE HAS INTERESTING DEVICE FOR FILLING OIL-CADGERS

By K. O. Duncan

One of the chief causes for the deterioration of rock-drills, causing unnecessary losses of both time and oil, is the indifference of mine managers to the methods employed for lubrication of the drills. In many mines where this important matter is left to the judgment of the miner, we find underground, tomato-cans, beer-bottles, whiskey-flasks, and other equally disreputable rock-drill oil-containers; none of them being well adapted to either filling or emptying with-

simple but ingenious device shown in the accompanying sketch was constructed.

The air-pressure on the oil of course, speeds the filling. In practice two racks or boxes, each holding about fifty cadgers, are found convenient. For gauging the desired quantity of oil for the container, the operator has two cadgers, one filled for the needs of the larger drills and the other suited exactly to the lighter machines, these constituting the counter-weights that exactly apportion to each drill, a sufficient quantity of oil. The racks containing the filled cadgers are placed at the collar of the shaft, and each miner going to work takes one, returning the empty flask to the rack when coming off shift. This scheme at the North Star mine has effected a considerable saving in oil consumption and drill maintenance.

Device for Filling Oil-Cadgers

out waste of oil and time; all inviting contamination from grit because of the inevitable uncovered condition of such containers; and all subject to destruction early in the shift because of their careless distribution about the place of action.

These common evils have been overcome to a large extent in the North Star mine at Grass Valley, California, by the use of the Donnelley oil-cadgers, a seemingly indestructible pocket oil-container of one pint capacity. It has a screw top and fits comfortably into the hip pocket of the miner.

Having adopted these containers, the management found that the filling of one hundred of them for each shift with the slow-moving castor machine-oil, was a tedious process. It was also found that there was wise economy in putting in each cadger only the amount of oil required for one drill during a shift. For the Waugh turbo drills it was found desirable nearly to fill the cadger, while for the Clippers, less oil was required for the shift's work.

To quickly and accurately place in the cadgers the precise quantity of lubricant for the particular drill in service, the

FLOTATION OILS

One of the vital factors on which the successful operation of a flotation plant depends, is the oils. If, for any reason, the correct oils are not being employed unsatisfactory results are bound to be obtained. Many adjustments and slight changes in operation can be made to take care of many of the minor troubles that are encountered from time to time in the plant. Unfortunately, however, such procedure will not correct unsatisfactory results that are caused by the use of incorrect or inferior oils. Since the inception of flotation in the United States, the Barrett Co. has been directing the efforts of its highly trained technical staff to produce high-grade uniform flotation oils. With this end in view, the company has spared neither time nor money to keep its flotation oils uniform and of such a character as will ensure the consumer's obtaining the highest metallurgical results.

The Barrett Co. is in an excellent position to carry on this important work for the mining industry. As is well known, the crude tars from the different tar-producing plants vary in characteristics to a greater or lesser extent. The variations are due to the conditions under which the tars themselves are produced, such as speed and temperature of coking, type of retort used, kind of coal employed, etc. All finished Barrett products are required to conform to rigid specifications. In order that these finished products can be made to do this, it is necessary that all of the raw materials be so blended as to give a uniform material before manufacturing is commenced.

This preliminary blending before manufacture requires large storage capacity and, also, many and constant sources of supply of raw tars. In all plants that produce blended flotation oils, both storage capacity and source of supply are necessarily provided in order to maintain flotation oils or products at the required grade and composition at all times, regardless of any slight variations that may be encountered in the raw tars that are employed. The metallurgical engineer, or flotation-plant operator, readily understands and appreciates the importance of this feature. The many causes of variation in flotation, other than the oils themselves, encountered in the daily plant operation, are so numerous and often so difficult of location, that the elimi-

nation of as many as possible of these variations in results due to the oils should have a great attraction for the user. At the present time the Barrett Co. is supplying various flotation reagents, including coal tars, coal-tar oils, fractions, and combinations of fractions of coal tar, as well as coal-tar chemicals, such as alpha naphthylamine, xylidine, orthotoluidine, etc. All of these materials have proved of exceptional merit under specific conditions to which they are adapted.

A number of mines have used crude coal tar and have had varying results, due, of course, to the great differences between tar from sundry sources and even between tars from the same sources at different times. Crude tar varies in viscosity and other physical properties, and in order that a mine may duplicate the results obtained from an initial lot of tar, a specially refined flotation tar should be employed.

A great advantage from the use of so-called 'specification' oils is the fact that each shipment is as nearly like every other lot as it is possible for science and care to make them. This fact tends to eliminate entirely all irregularities in plant operation due to oils, and is bound to make possible more even results than can be obtained with the less refined products. Recently great interest has been aroused among flotation engineers and operators by the success that has been obtained by the use of X-cake mixture (a mixture of 60% alpha naphthylamine and 40% xylidine) in the plants of various large mining companies. The Barrett Co. is equipped to produce and furnish either crude or refined alpha naphthylamine and xylidine separately, and small parcels of the different grades can be shipped for experimental investigation. Most mining companies, however, prefer to purchase alpha naphthylamine and xylidine already mixed in portions of 60% and 40% respectively, thus eliminating the trouble of mixing them on the ground.

Many engineers and operators are of the opinion that there are certain fields and conditions where coal-tar oils and products cannot be used. Very thorough investigations have demonstrated, however, that this is seldom the case, and that coal-tar oils and products can replace other oils in most cases. The only manner in which this point can be practically demonstrated is by commercial tests in the operating plant. Barrel samples of flotation oils should be obtained and used, under operating conditions, before a question of this importance should be considered closed by the plant management.

In order to get in closer touch with the users of flotation oils and products, the Barrett Co. has a flotation-oil department. This department is in charge of a thoroughly competent flotation engineer. It is the function of the department to co-operate with the mining and metallurgical fraternity in any way consistent with an established and conservative manufacturing and selling policy. This department will be glad to discuss the flotation-oil problems of the individual operators and it invites correspondence along these lines at all times. All such inquiries will receive careful consideration and will be discussed in a conservative technical manner.

The New Jersey Concentrating Co. in order to cope with increasing business and to offer greater facilities to its clients, has acquired spacious water-front property in Elizabethport, New Jersey. The company is ready to grind, concentrate, separate, and store all kinds of metals and minerals, such as manganese, chrome, etc. A 300-ft. private dock allows vessels to berth right alongside the plant. Railroad-siding along the whole length of the dock affords unloading from steamer into cars for bulk shipments. Additional railroad siding allows the simultaneous handling of 15 to 20 cars. Crushers, rolls, and sampling floors afford correct and expeditious sampling while loading or unloading steamers or cars.

BARBER-GREENE BUCKET-LOADER

The accompanying illustration shows a bucket-loader manufactured by the Barber-Greene Co., of Aurora, Illinois.

Barber-Greene machines are standardized. They do not undergo much change from year to year, although the experimental department is continually after refinements. The newest self-feeding bucket-loader has the revolving-disc feeder which distinguishes all B-G loaders. The crawler type of traction has been adopted as standard. Crawlers make it possible to turn a machine around in its own length, one crawler can be stopped while all the power is given to the other to furnish the turning force. Of course, crawlers permit a machine to be operated on soft ground where a machine on wheels could not 'navigate'. Continuous treads, 58 by 8 in., make a bearing pressure of only seven pounds per square inch on the ground. No change has been made in the power-units used to drive the machine. The four-

Bucket-Loader

cylinder truck-type 'Buda' gasoline engine is used as before. It possesses ample power for every operating possibility.

A somewhat radical departure from the general Barber-Greene design of standardized conveyors has been made in the new universal conveyor recently put on the market. Type 'U', instead of having trussed sectional construction, has a channel frame 4 in. by 22 ft. Twenty-two feet has been adopted as the only length, since this machine is designed only for unloading cars and loading wagons or trucks and other jobs where length and height of discharge are not needed. This is called the conveyor with the digging end because of the new method of belt and hopper construction. The lower end of the machine is built with belt exposed. Cupped flights across the belt furnish the digging parts, so that the machine may be pushed into a pile of loose material where it will burrow its way under as long as the pushing is kept up. The standard belt width is 12 in., and every inch is made available by overlapping steel side-plates attached on the edges of the belt. They form a trough as wide as the belt, and prevent any wear on the belt edges. Skirt-boards the full length of the machine, set at an angle, make it possible to carry lumps much larger than twelve inches.
